Eggs—There has not been much doing to-day. We heard of no large sales. Round lots are worth from 15c. to 16c.

Cheese—Unchanged. We heard of no lots selling to-day. Factory is held at from 10½c. to 11½c.

Dressed Hogs—Very few coming in to-day, this being Monday. The very best hogs sell to retailers at from $6 75c. to $7. Ordinary for packing purposes bring from $5 to $6 50c.

Hops—Stocks are increasing. There is, however, only a limited business doing. Good to extra per pound are held at from 15c. to 20c; fair to good at from 10c. to 15c.; old will not bring over 5c. to 10c.

Potatoes—Only a few loads were offering to-day. Prices are unchanged, namely, 75c. to 80c. per bushel.

Apples—In fair supply. Selling freely at from $1 60c. to $1 75c. per barrel.

Hides and Skins, per lb.—*Hides*, green, rough, per lb., 5½c.; do. green, inspected, 7c.; do. cured and inspected, 7½c. to 8½c. *Calfskins*, green, 10c.; cured, 12c.; dry, 18c. to 20c. *Lambskins*, green, 45c. to 50c. *Sheepskins*, 60c.

Guelph Markets, Oct. 12.—Fall Wheat, per bushel, $1 18 to $1 20; spring wheat, $1 00 to $1 05; oats, 48c. to 55c.; barley $1 35c. to $1 40c.; peas, 60c. to 65c; wool, 28c.; hay per ton, $10 to $12; straw per load, $3; turnips per bushel, 15c. to 20c.; butter, per lb., 18c. to 20c.; Apples, per bag, $1.

London Markets, Oct. 12.—Red Fall Wheat per bushel, $1 04 to $1 06; white wheat, $1 12 to $1 15; spring wheat, $1 05; barley, $1 27 to $1 37; peas, 60c. to 62c.; oats, 40c. to 42c.; corn, 80c. to 90c.; Buckwheat, 50c. to 60c.; rye, 55c. to 60c.

Montreal Markets.—Oct. 12.—*Flour*—Superfine Extra, $7 to $7 15c.; Extra, $6 50c. to $6 80c.; Fancy, $6 60c. to $6 90c.; Welland Canal Superfine, $5 30c.; Superfine No. 1 Canada Wheat, $3 30c. to $5 45c.; No. 1 Western Wheat, $5 30c.; No. 2 do, $4 80c. to $5.; Fine $4 30c. to $4 40c.; Middlings $3 90c. to $4; Pollards $2 90c. to $3. *Bag Flour*—$2 60c. to $2 60c. *Wheat*—Canada Fall, $1 30c; Spring $1 22½c.; Western $1 15c. to $1 20c. *Oats*—Per 32 lbs. 47c. to 48c. *Barley*.—Per 48 lbs. $1 30c. to $1 35c. *Butter*—Dairy, 21c. to 23c.; Store-packed, 20c. to 21c. *Cheese*—Factory, 10c. to 11c.; Dairy, 9c. to 10c. *Eggs*—16c. to 17c. *Ashes*—Pots, $6 65c. to $6 75c.; Pearls, $6 65c. to $6 60c. *Pork*—Mess, $24 25c. to $24 50c.; Thin Mess, $23; Primo, $17 to $17 50c. *Lard*—16c. to 17c. *Peas*—$1 05c. to $1 06c. *Rye Flour*—4 30c. *Oatmeal*—$6 40c. *Cornmeal*—$4 to $4 10c.

Chicago Markets, Oct. 13, noon.—William Young & Co.'s report.—Wheat—Receipts, 130,000 bushels; shipments, 93,000; No. 2, irregular at $1 38. Corn dull at 95½c.; receipts, 62,000 bush.; shipments, none. Pork firm at $20.

New York Produce Market.—*Flour*—Dull. Receipts 25,600 barrels; sales 6,100 barrels at $6 75c. to $7 15c. for superior State and Western; $7 50c. to $8 10c. for common to choice extra Western. *Rye Flour*—quiet at $6 to $8 50. *Wheat*—Dull, and 1c. to 2c. lower; receipts, 165,000 bushels; sales 48,000 bushels at $1 60c. to $1 65c. for No. 2 spring; $1 77½c. for No. 1 do; $1 79½c. for amber Green Bay; $2 57c. for white California; $2 40c. to $2 60c. for white Michigan. *Rye*—quiet. Receipts 7,400 bushels. *Corn*—Opened firm and closed dull. Receipts 313,000 bushels; sales 76,000 bushels, at $1 17c. to $1 19c. for unsound; $1 19c. to $1 20c. for sound mixed Western. *Barley*—Scarce. Receipts 65,000 bushels; sales 9,500 bushels Canada West at $2 35.

Milwaukee Markets.—Oct. 13, noon.—Wm. Young & Co.'s report.—Wheat—Receipts, 106,000 bushels; shipments, 81,000; No. 1, irregular at $1 43½ to $1 49; No. 2, do. $1 38. Flour dull and unchanged. Pork firm at $20 75c. Freights nominal.

The Canada Farmer is printed and published on the 1st and 15th of every month, by the Globe Printing Company, at their Printing House, 26 and 28 King Street East, Toronto, Ontario, where all communications for the paper must be addressed:

☞ Subscription Price $1 per annum, (Postage Free,) payable in advance. Bound volumes for 1864, 1865, 1866 and 1867, may be had for $1 30 each. Subscribers may either begin with No. 1 of the present Volume, or with the first No. of any preceding volume. No subscriptions received for less than a year, and all commence with the first number for the respective years.

Clubs will be furnished at the following rates:—

Ten Copies for.....Nine Dollars.
Twenty Copies for.....Sixteen Dollars.
Forty Copies for.....Thirty Dollars.
One Hundred Copies for.....Seventy Dollars.

To Agricultural Societies ordering more than 126 copies, The Farmer will be sent at Sixty Cents.

The Canada Farmer presents a first-class medium for agricultural advertisements. Terms of advertising, 20 cents per line space. Twelve lines' space equals one inch. No advertisement taken for less than ten lines' space.

Communications on Agricultural subjects are invited, addressed to "*The Editor of the Canada Farmer*," and all orders for the paper are to be sent to

GEORGE BROWN,
Managing Director.

The Month.

OVEMBER is a month of very uncertain character in this climate. It is hard to say how it will behave. Sometimes it begins with a rough cold snap that startles us into a conviction that winter does really mean to come again, and, as if to make amends for its rough behaviour at the outset, closes with that delightful reminder of a departed season which we call "Indian Summer." Or this order is reversed, in which case summer in pretence begins the month, and winter in earnest closes it. The well-known March proverb is not inapplicable to November. If it come in like a lamb it will go out like a lion, and *vice versa*.

The mean temperatures for this month are as follows:—

Stratford	36° 75'
Hamilton	39° 75'
Barrie	37° 99'
Toronto	38° 35'
Belleville	38° 82'
Montreal	34° 75'
Quebec	35° 50'
St. John, N.B.	37° 40'
Halifax	38° 00'

"Preparation for winter" may be written as the motto and watchword for November. It is to be presumed that the potatoes are all dug and housed either in cellars or pits. We are liable to have frosts about the first of November, severe enough to do great damage to potatoes. If any are left in the ground at so late a date as this, by all means let them be got out of it forthwith, if Jack Frost is not playing jailer with them.

All the root crops should be taken care of at once: carrots, beets, mangolds, and turnips. Carrots are beginning to be raised more extensively, chiefly as winter food for horses, and they are very valuable for this purpose. But they are equally good for other animals. Boiled and mixed with meal they are excellent for fattening hogs. Mangolds may be alternated with turnips in feeding cattle. Thus used for milch cows, they correct the turnipy flavour which is apt to be given to the milk by the exclusive use of turnips. But mangolds are especially useful toward the close of winter, and by their peculiar qualities, are an excellent preparation for turning out to grass. In taking up turnips, the best plan is to remove the tops before lifting the roots. This can be done most expeditiously by means of a sharp hoe. Care must be had not to cut a slice off the turnip along with the top. The tops may either be fed to cattle or ploughed in. We prefer the latter course, chiefly because the tops are a rather too unsubstantial and loosening diet to be a good preparation for winter, while they are an excellent green manure. Some farmers are in the habit of tearing their turnips out of the ground with harrows. We do not commend this practice. It cuts up and wounds the bulbs considerably. A light tool, somewhat like a pick, made for the purpose, does the work much more satisfactorily, and the process is not so slow as might be imagined. One of the best farmers we know, who usually raises about twenty acres of turnips each year, pursues this plan in preference to all others. The most convenient way of storing them for the winter is in a root-house close to the cattle stabling, but they will keep well in pits. Care must be taken to provide ventilation, and to avoid the extremes of warmth and cold. Turnips keep best just above the freezing point.

All animals should be well housed this month. Nothing is more unprofitable than to let stock suffer inconvenience from the cold. It is a great waste of feed, for shivering animals eat voraciously, and after all their food does them far less good than if they were kept comfortable. It is especially bad policy to let young stock suffer exposure. Keep them warm and they will improve in flesh, appearance and constitution. No prize animal was ever produced by being treated to a straw stack for both shelter and food. Colts will show the effect of care and good stabling more decidedly perhaps than any other description of young stock. It is a total mistake to suppose that exposure makes them hardy. Shelter, good food, ventilation and exercise, are what impart toughness of muscle and power of endurance. Fattening hogs should be well housed in good season, and got ready for market by settled cold weather. Better prices usually prevail early in the season, before the market is glutted with pork. Poultry intended for the table or market should be cooped, and fed with scalded meal, and the like. The addition of a little suet will hasten the fattening process; especially in the case of geese and ducks. The practice of converting poultry into food without preliminary fattening is to be reprehended quite as much as the practice of slaughtering lean beef, mutton or pork.

Manure-making is an important November job Collect stores of muck, leaves, dry tan bark, sawdust, and any sort of litter that can be used as an absorbent, that all the droppings, both liquid and solid, may be secured. "Waste not, want not." The yards should be cleaned now and then, the manure thrown up loosely into heaps, and coated with muck or soil. The value of manure depends largely on the food eaten by the animals; the richer the food the better the manure. A large proportion of the food of well-fed animals finds its way into the manure, and hence that made from fattening animals is of the greatest value. Hogs are the best fed of any animals on the farm, and next to night soil, hog manure is the richest of fertilizers.

Until frost comes, the plough should be kept going upon land meant for spring crops. All soils are benefited by exposure to the action of frost in a loose condition, clay soils particularly. Many a tough, unpromising soil in the fall, has become loose, friable, and pleasant to work by spring, under the influence of alternate freezing and thawing.

It has been well observed that "there may be great slaughter of biennial weeds this month with a 'spud.' Every coarse-leafed flat-growing plant in the meadows and pastures (and many that have fine leaves in close bunches), and green at this time, are plants that make root one year and bloom the next. Cutting an inch or two below the surface is fatal to most of them, and damaging to all."

Orchard and garden work the present month also comes principally under the head of preparation for winter. Some recommend planting fruit trees as late in the season as it can be done without danger from a too cold and frosty air, which is apt to injure the roots. We prefer to heel in the trees now, and wait for a favourable time to plant in early spring. The orchard may be top-dressed with manure to advantage the present month. Some are absurd enough to expect continuous crops of fruit without enriching the ground in which the trees grow; but fruit is like everything else, it must be cultivated and manured if it is to yield satisfactorily. Where field mice abound, it is necessary to bank up young fruit trees with soil ten or twelve inches high, making the surface firm and smooth, to prevent them from girdling the trees—a favourite trick with them. It is well to spade or plough gardens late in the fall. Some recommend pruning grape vines before winter sets in, others advise delay until just before the sap begins to flow in early spring. Grapes and raspberries are best laid prostrate, and even covered with an inch or two of soil before winter. A loose covering of cornstalks, straw, litter, or leaves, is advisable in the case of strawberry beds. Tender bulbs should be lifted and put in the cellar, if that has not already been done. In short, everything animal or vegetable, that requires winter quarters, must without further delay go into them.

The Field.

Storing Roots.

A few words on the subject of storing roots, in addition to the hints already given in the article on the month, may not be unacceptable to young Canadian farmers. With regard to the modes of harvesting the various root crops, it is not always possible, for want of sufficient help, to do this in the best manner. The necessity of using the most expeditious means is sometimes more pressing than the desirableness of employing the most approved plan. Pulling by hand, topping, and tailing, are no doubt the cleanest and altogether thriftiest processes; but with a number of acres to gather and a very few hands to do the work in but a short time, this tidy method is not always practicable. The implement adverted to in the foregoing article, will be found to effect a great saving of time in harvesting turnips. If the work is still more pressing, it may be expeditiously and not badly done with a plough. It is sometimes necessary to use the harrow; but these rough methods are objectionable, as they tend to wound and bruise the roots, and so render them more liable to decay. The less they are knocked about the better.

It is the practice with some good farmers to pile the turnips in heaps in the field, and cover them over with leaves, and let them remain for some days to "sweat" before hauling them to the root-house or pit. It is contended that the after heating in the bulk is thereby diminished.

The root-house is no doubt the most convenient receptacle for storing roots. It should be located near the stables, so as to diminish as much as possible the labours of carrying food to the animals during the winter. Experience will soon teach the farmer the importance of attending to these apparently trifling details. A few minutes saved in operations that recur frequently during each day, will amount in the aggregate to a very considerable item. It is not well, however, to build root-houses under the main portion of barns; for the steam and moisture from turnips especially, will speedily rot the timbers in the roof of the apartment in which they are stored; and when these support the floor of the barn or stables above, they have soon to be replaced, and perhaps at considerable inconvenience and outlay.

Great attention should be paid to thorough ventilation, a moderately cool temperature should be secured, and free egress allowed for the steam and vapor to escape. Generally speaking, the door and other apertures of a root-house where turnips are stored should be kept open during a large portion of the time till Christmas or thereabouts; and even afterwards, whenever there is any considerable rise in temperature, the access of external air and a thorough draught should be permitted, due caution, of course, being exercised to guard against freezing. Potatoes are not so liable to heat as turnips, nor indeed are mangolds; and both these roots, mangolds and potatoes, are more delicate, more liable to be injured by frost than turnips. Some practical inconvenience therefore occasionally arises from storing the different kinds of roots together. This may be partly guarded against by partitions in the root-house, and by setting apart the warmest portions of the space for the more tender roots.

Where the farmer has not the convenience of a suitable building, or where such accommodation is insufficient for the whole crop, roots may be kept with perfect safety in well-constructed pits. These need be but little dug below the surface; though sometimes they are stored in pretty deep trenches. We prefer a shallow excavation, such as can be made by loosening the soil with a plough, and using a shovel afterwards. A slope of ground should be selected to facilitate drainage, and the length of the pit should correspond to the inclination of the ground. Regard must, however, be had to the aspect. It is not well to have one side facing south and the other north. One will have the full force of the sun, and the other always the shadow, and exposed to the keenest winds, would be doubly cold. The floor of the pit should be so graded that no water can lodge in it, and trenches should surround it outside in such a way as to carry off all melting snow or rain-fall.

The inexperienced are sometimes apt to make these pits too wide, by which the danger of heating is greatly increased. Five or six feet is quite wide enough. The length is a matter of less consequence. The turnips should be piled up to a ridge. If boards are handy they will be found serviceable to place next the roots, in such a way as to prevent the dirt falling in when the roots are removed from beneath. A good covering of straw should next be packed evenly over the whole. Use plenty of straw. Then cover all with a coat of soil well pressed and beaten down. A thorough ventilation should be secured by chimneys near each end and at regular distances between. These pipes can be conveniently made out of inch fence boards, six inches and four inches wide. Two opposite sides should be about six inches longer than the others, and over the longer a short board can be nailed. This will cover in the top and keep out rain and snow, while a sufficient opening will be left at the sides for ventilation. Sometimes it is desirable at first to leave the ends of the pits open for a time to keep down the temperature, and allow a readier escape of vapor. After a while more earth should be piled on, and before the winter fairly sets in, a pretty thick coating of earth should be packed upon the straw. Some persons are afraid of covering too deeply for fear of keeping the turnips too warm, but there will be no fear of this if due attention is paid to the ventilation. Potatoes require a warmer covering and less ventilation than other roots, and should, if possible, be stored away dry. In very cold weather, all openings should be stopped up with straw, which may be removed again when the weather moderates.

Experiments in Wheat Culture.—Drilling and Horse-Hoeing.

The Secretary of the Goodhue Farmers' Club, of Minnesota, communicates to the *American Agriculturist* the following interesting statement in regard to some experiments in wheat culture, made by one of the members of the club.

Field No. 1.—Two bushels to the acre was sown with the broadcast sower and cultivator combined, and the seed was planted at all depths, from the surface to three or four inches deep.

Field No. 2.—Was sown with a common wheat drill, east and west, one and a quarter bushels being used to the acre, planted about two and a half inches deep.

Field No. 3.—Three pecks of seed were drilled in, east and west, two and a half inches deep, and eighteen inches apart. It was cultivated but once, when about a foot high, with a five-toothed walking cultivator, at an expense of $1 per acre.

The results are thus stated: "No. 1 was good wheat, not damaged by heat, head medium in length, well filled, stood thick upon the ground. Was unequal, some straws five and six feet in length, and some only two feet. Some heads were very green, while others were ripe. The yield is estimated at from twenty to twenty-five bushels per acre. No. 2 was of a better color during growth than No. 1. Very even in straw and degree of ripeness. Heads about even, of extra length. Bundles very heavy, and the yield is estimated at thirty bushels per acre. No. 3 was extra at all times. Its unusual deep green colour and broad leaves attracted much attention. No one supposed it the same kind of grain as lots 1 and 2. It stooled out much more than either No. 1 or 2. It was uniform in length of straw and degree of ripeness. The heads would average one-third larger than No. 1, and the largest and heaviest wheat we ever saw. Strangers here picked for the smallest heads, and then shelled from sixty to eighty kernels from each head. Our binders, and we had some from other States who had had much experience, said they never saw such large heads or such heavy wheat of this kind, namely, China Tea. The yield is estimated at thirty-five or forty bushels per acre."

The Club arrives at the conclusion that they have been in the habit of using too much seed for spring wheat; that wheat needs cultivating; that if half a bushel of seed were used per acre, and sowed in drills fifteen inches apart, and thoroughly cultivated, the average crop of Wisconsin might be doubled. They recommend, moreover, the expenditure of the price of the seed saved in giving the land a more thorough harrowing. In this they are wise; there is nothing to which wheat so quickly responds as thorough tillage, and it may be a question whether this should be done previous to sowing or after the grain is up. There are other interesting subjects for investigation before any one can speak with authority. The exact amount of seed per acre, though depending in a measure upon the kind of wheat and the character of the soil, may be nearly approximated. The distance apart of the drills is another subject for experiment; twenty inches has been recommended. It is difficult to cultivate between those which are much nearer, and no doubt the roots will fill the ground between them at this distance.

The Product of one Weed.

Desiring to know what might be the influence of a single weed upon the agriculture of a field or garden, I selected a plant of purslane (pusley or parsley, as called by some), and carefully counted its number of pods. It was a large, but not the largest sized plant, from a rich spot of ground. The number of its seed pods was 4,613. I then took fourteen of the pods, seven small ones, four medium, and three of the largest, and counted the seed in them. The result gave me as an *average* ninety seeds to the pod. Thus in this single plant we have the enormous number of 415,170 seeds. If these were spread over a plot of ground and should all germinate, and a man should attempt to cut them with a hoe, and should average six plants at every blow, and make thirty strokes of his hoe per minute, it would take him thirty-eight hours and twenty-three minutes to cut them out. Or, if these seeds were equally disseminated at the rate of four to the square foot, they would cover over two and a third acres of ground. Again, allowing only one-third of these seeds to germinate, and that the product shall only be one-half as rich in seed as this plant, yet they will produce the astonishing number of 28,727,688,150 seeds, enough to cover broad fields with weeds the third year, from one seed. Do not these figures show the immense importance of cutting and destroying every weed before it goes to seed? There is no doubt that many other weeds are as fully or more prolific than this. The purslane is a difficult weed to kill. I have known it in wet weather to grow and mature its seed long after it had been entirely severed from the root.—*Cor. Journal of Agriculture.*

Utilization of Sewage.—Our English exchanges give interesting accounts of the very satisfactory experiments made in the neighbourhood of London, on the Lodge farm, to test the fertilizing power of the sewage of the city. A company was formed some time ago to reclaim some of the poor, waste land in the County of Essex, by means of the sewage of the metropolis, and it is from the last yearly report of this company that the following results are given. One-fourth of the acreage under cultivation raised rye-grass, for which there is a greater demand than can be met. As a proof of the fattening power of sewage-grown grass, it is stated that two young steers fed exclusively on it had, from the 18th of May to the 7th of August, gained weight to the following extent: one, 1¾ cwt., and the other 2 cwt. Land of the poorest and most sterile description, with no other manure than sewage, is found to yield prolific crops, not only of grass, but of wheat, rye, mangold, cabbage, turnips, potatoes, &c. By this means six or seven crops of grass are raised in a season, each very heavy. With two dressings or floodings of sewage, a crop of mangold of fifty or sixty tons per acre has been produced where not more than twenty or twenty-five could be had when farm-yard dung was used for manure. In the same way, without this manure, the crop of wheat was about twenty-eight bushels per acre; with it, something like forty-four. Could we not also utilize the waste of our cities?

The Uses of Clover.

It would be very difficult to over-estimate the importance of this crop to all farmers engaged in mixed husbandry. Its introduction into England produced an entire revolution in the Agriculture of that country. Clover laid the foundation of all those wise systems of rotation that have since made the Agriculture of England a model, and a marvel to the world. Nor is its importance much less in those sections of America where its values are appreciated and rightly applied,

Clover is valuable:

1. As a forage plant.
2. As a fertilizer.

As a forage crop, its special value is in the quantity and quality of the hay that it produces, and the rapidity with which it comes to maturity after being sown. Clover properly cured, is almost equal to good Timothy, for beef cattle, and much superior to all other hay, for milch stock. In pasture, the same relative values hold with the addition that, for hogs, clover is a grand specific, superior, perhaps, to all other grasses.

The specific value of Clover, however, lies in its wonderful powers as a fertilizer. In this respect it is unequaled by any crop grown on the farm. The different ways in which it adds to the fertility of land are chiefly:

1*st. Shading the surface of the soil.* Owing to its rapid and luxuriant growth it soon forms a close and heavy covering over the soil, that acts as a mulch in protecting it from the scorching rays of the summer sun. At the same time that the soil is protected the weeds are smothered out, and the land cleaned up.

2*nd. By aerifying and disintegrating the soil.* Clover possesses peculiarly long and powerful tap-roots, that penetrate deep, loosening the soil and admitting the air. Thus rapidly changing the physical condition not only of the soil, but of the subsoil also.

3*rd. By effecting important chemical changes, necessary to enrich the earth with plant food.* Its abundance of foliage enables Clover to gather from the atmosphere immense stores of gases that give life to the plants, which its far-reaching roots send deep down into the earth. Thus a clover field becomes, as it were, a great reservoir for plant food. And clover itself becomes a great commissary, collecting food from the earth and the air for whatever crop that may follow.

4*th. By preventing washing.* The Clover mulch breaks the force of the hard beating rains, while the roots hold the soil in a mat as it were, thus preventing it from washing

5*th. As a green manure.* Perhaps no crop is so valuable for turning under in a green stage, as Clover. In addition to the immense amount of rich vegetable matter in its abundant roots, the plant itself is extremely rich in all the materials necessary to the healthful growth of succeeding crops.—*Dixie Farmer.*

How to Use an Axe.

Mark Tapley, in his "Home in the wilderness," thus discourseth: "To use perfectly the American wedge-shaped axe (and here let me say that it is the only axe for felling timber and doing everything with which is worth one straw), requires no ordinary degree of skill and practice.

"Strength, of course, has something to do with it, still a man of only moderate muscular power would beat a giant into being ashamed of himself, if the weaker man did, and the stronger man did not, know how to wield an axe.

"The axe I prefer for all ordinary purposes ought to weigh about 8 lb., and it should be carefully mounted or 'hung,' as the term is, on a springy, rightly curved hickory handle. * * *

"Let us suppose you are going to fell your first tree: be careful to discover how the tree leans, and always choose that side towards which it inclines to begin on; by doing this you avoid the risk of falling the tree on yourself. Stand off from the trunk, so that the edge of your axe blade can touch the centre of it, whilst both your hands are grasping the handle before the knob at the end of it, purposely made to prevent it from slipping out of the grasp in the act of chopping.

"Fix your eye on a spot about three feet from the ground on the tree trunk, plant your feet firmly, look carefully behind you, to make sure that there are no small twigs or branches to intercept the axe; then holding the handle by the extreme end, not too firmly, or it will jar your wrists, and whirling the axe at arm's length round your head, bring it obliquely down upon the spot you have fixed your eye on. If you bring the edge down on the proper slant, the blade should be nearly buried in the bark and timber; if you do not it will 'glance,' and then look out for your legs. Repeat this cut if you can; an axe-man would, twice or three times following, in the same place. Should the tree be, for example, four feet in diameter, chopin the next cut you make three feet lower down than where you made the first cut, but, this time, horizontally, always bringing the axe round at arm's length. This will give you the 'right sized chip,' to use a lumberer's phrase, or, what he means, in other words, is, that the three-feet notch will enable the chopper to make the wedge end of the tree break in the centre of the stump; if you took a smaller notch, as nine out of ten inexperienced men would do, you would find your axe jammed before you could chop half way through the trunk; hence the length of the chop is always in proportion to the girth or diameter of the tree to be felled. Cut half way through the tree, always keeping the lower surface horizontal and smooth, as if planed; then change and begin on the opposite side to that on which you have been chopping, precisely in the same way as you began the other cut; when you are nearly through, the tree will crack off, and of course fall in the direction to which it leaned, that is, away from you."

The Early Rose Potato.

The following account of an experiment with the early Rose Potato corresponds in its general tenor with many other reports which we have seen, and which lead us to form a very favourable opinion of this new variety:—

"As the 'Early Rose' is now presenting itself to the agricultural public, and is receiving, as every new source of and claimed improvement should receive, a thorough test and trial of its merits, perhaps a few words in relation to my own personal experience with it the past season would not be amiss.

"Being attracted last winter by its presentation in the December number of '*The Practical Farmer*,' I was induced to purchase some of them at the enormous price of $3 per pound; and with one of these pounds I will state my treatment and success, deeming it might be interesting to some of your practical readers.

"The pound of potatoes contained nine tubers. Owing to the unfavourable spring, and not receiving them till late in the season, I did not succeed in planting them till May 26th. On the 20th I proceeded to cut them for planting; the eyes had started growth, by which I was enabled to cut them in single eye pieces. Some of the middle or large eye pieces I divided, making from the nine potatoes one hundred and six plants, all of which grew; they were planted without any extra preparation of the soil, the ground being manured, ploughed down, and marked out about four inches deep, and planted with phosphate in the row; kept the ground mellowed by frequent harrowing, and about blossoming time drew a little dirt towards the row. They occupied just one hundred feet of row.

"September 11th I proceeded to dig and weigh them, and from the one pound planted, I had just one hundred and one-half pounds of potatoes, and what was still better, ninety-three pounds of them were large merchantable potatoes, such as will bring the highest market price. Their shape accords very much with that of the *White Mercer*; their color a dull rose; inside, flesh pure white, and exceedingly starchy and fine. In short I consider them a great acquisition to the grower of potatoes and cultivator of the soil.—*Cor. of The Practical Farmer.*"

Advantages of Underdraining

Waring, in his "Elements of Agriculture," states that the advantages of underdraining are many and important, and enumerates the following:

1. It entirely prevents drought.
2. It furnishes an increased supply of atmospheric fertilizers.
3. It warms the lower portions of the soil.
4. It hastens the decomposition of roots and other organic matter.
5. It accelerates the disintegration of the mineral matters in the soil.
6. It causes a more even distribution of nutritious matters among those parts of soil traversed by roots.
7. It improves the mechanical texture of the soil.
8. It causes the poisonous excrementitious matter of plants to be carried out of the reach of their roots.
9. It prevents grasses from running out.
10. It enables us to deepen the surface soil.

By removing excesses of water—

11. It renders the soil earlier in the spring.
12. It prevents the throwing out of grain in winter.
13. It allows us to work sooner after rains.
14. It keeps off the effects of cold weather longer in the fall.
15. It prevents the formation of acetic and other organic acids which induce the growth of sorrel and similar weeds.

Splitting Rails.

Almost every farmer can split rails, but there is considerable science in the work after all. One man will rive them out with apparent ease, while another will tug away and exhaust his strength in a few hours. The reason of this difference is owing to the weight and shape of tools, and the knowledge of their use. One man makes a constant outlay of strength, while another will apply it only at an essential point, and that is when the beetle is descending and near the wedge.

An experienced rail-splitter tells us that the best maul is made of a knot, and should be of medium weight, not so heavy but that a man can swing it with ease. One iron wedge, quite slim, should be kept and used for starting the split; it is not apt to rebound, and if it should, it may be easily prevented by making a few checks with an axe near together, and starting the wedge between them, or by rubbing the wedge in dirt.

It is hard enough to split rails at the best, and we believe it a sin for any man to attempt the work without proper prerequisites, for he has no right to exhaust physical powers and ruin his constitution by using poor tools, when the best can be obtained at a trifling expense. Great advantage is gained, when making rails, by opening large logs with a charge of powder.—*Ohio Farmer.*

Destruction of Stumps.

We have always objected to the use of machinery of any sort to take up large stumps in ordinary arable land, that they would take up inevitably a large quantity of earth with each, and leave a hole almost as objectionable as the stump; and moreover, that after the stumps were out there was trouble in disposing of them. The following suggestions which we take from our neighbor, the *Baltimore Weekly Leader*, may be quite practicable, while they are not liable to the same objections. They are at least worthy of trial:—

"We have heard of two methods of getting rid of stumps, which, as they appear feasible and inexpensive, we hope some reader will try and report upon. Bore with a two inch auger to the heart of the stump; fill the cavity thus made with sulphuric acid, or with crude oil of petroleum. In the first case, the acid becomes the destructive agent within a few months; in the latter, when the stump becomes saturated with the oil, it is fired, and will then burn out to the last particle like a candle."—*The American Farmer.*

Bright Barley.—A correspondent from Wyoming Post Office, Plympton, asks "how the farmers around Toronto save and harvest their barley to get so bright a colour? The grain-buyers say our barley is plumper than that raised round Toronto, but deficient in colour." We do not know of any special method pursued by the farmers in the neighbourhood in gathering this crop. During the past season no particular care has been necessary; the dry weather, with all its disadvantages, has been favourable for harvesting. Perhaps the soil may make the difference referred to, if it really exists.

Norway Oats.—*L'Union des Cantons de l'Est*, published in Arthabaskaville, contained the following paragraph in its issue of the 8th ult., copied, apparently, from the *Pioneer*:—

"Mr. J. P. Lee, of Stanstead, sowed, last spring, 32 lbs. of Norway oats on a piece of ground measuring 100 perches, from which he harvested 1620 lbs., or 50 bushels. The husk is small, and the straw very superior to that of ordinary oats. The ears are 12 to 20 inches long—some of them yielding 226 grains,—and there were from 29 to 50 ears from a single grain. Mr. Lee believes he would have harvested double the quantity he had if the season had been favorable. A Mr. Price, of Vermont, is said to have harvested 100 bushels of this oats to the acre."

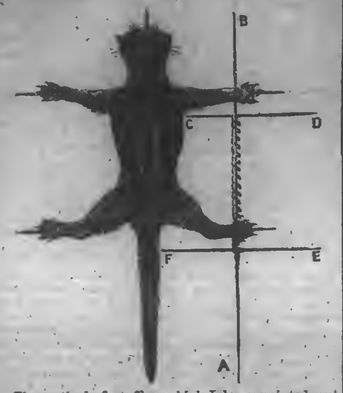
Go to Farming.—A good living is what comparatively few men succeed in making in village or city life, and yet nothing is more easy of accomplishment on the farm. Besides, there is a pleasure in cultivating and embellishing the earth, improving and increasing its products, and thus adding to the aggregate of human happiness. Why, then, should young men hesitate to be farmers? It is both profitable and honorable. It is the nearest approximation to independence that man as a member of society can make. A gentleman farmer—and all farmers are, or should be gentlemen—belongs to an order of nobility that is not indebted to placeholders for installation, and may, if he chooses, be ranked among the greatest benefactors of the human race. Let all the idle young men go to work on farms, and quit seeking third and fourth rate clerkships. In short, go to farming and quit begging.—*Ex.*

Canadian Natural History.

On Stuffing Quadrupeds.

To the Editor of THE CANADA FARMER:

SIR,—It will be remembered that in the number of your journal issued September 1st, I gave directions for skinning quadrupeds. I now propose to describe the method of stuffing them. Let us suppose the animal to be a cat. Take a central wire, which must be the length of the head, neck, body and tail of the cat, shown in the accompanying cut, that is, from A to B. Two other wires are then taken, and twisted round the centre piece in the manner represented in the cut, c. d. e. f., their extremities being left for the leg wires. After the wires are thus twisted together, the central wire is pulled out; and the feet wires of one side are pushed through the legs of one side from the inside of the skin, and the other two leg pieces are bent and also forced through the other legs, and then made straight by a pair of pincers. The centre piece, having been previously sharpened with a file, is now forced through the forehead and down the neck till it enters the centre of the twisted leg wires, in the position which it formerly occupied, and is then pushed forward to the extremity of the tail, leaving a small piece projecting out of the forehead, as represented in the cut; after which the completion of the stuffing is proceeded with. We will suppose the skull is now well rubbed with the arsenical soap, and all the cavities which the muscles before occupied are filled with chopped tow, flax or cotton, well mixed with preservative powder. The inner surface of the neck skin is now anointed and stuffed with chopped tow, taking care not to distend it too much. Nothing like pressure should be applied, as the fresh skin is susceptible of much expansion. Observe that it is always the inner surface which is anointed with the arsenical soap. And now having the neck stuffed, begin with the fore legs, and when they are both completed, stuff what will then be the under side of the centre wire; then form the breast, and continue stuffing the body until you come to the hind legs. Serve them the same as the fore legs. Observe that the wires in quadrupeds should be longer for the hind legs than for the front ones. Before finishing the body, stuff the tail; then finish the body, and anoint all the skin that can now be reached, and then with care sew up the skin, and if any hairs have been drawn in with the thread they must be picked out with a small awl. When this is completed, the hair will resume its natural order and completely conceal the seam. The articulations of the legs are then bent, and the animal placed on its feet. Pressure should now be applied over the places that are naturally flat, so as to make the other parts rise where the muscles are visible. A board is then prepared on which to place the cat. When you have decided on the position in which you intend to set your animal, bore four holes for the admission of the feet wires, which must be drawn through with a pair of pincers till the paws rest firmly on the board, and then twisted into a groove underneath the board, so that it will sit level. The stuffer next devotes his attention to the position and final stuffing of the head and neck.

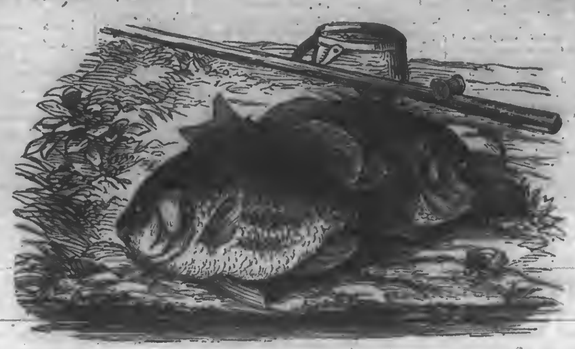


The method of stuffing which I have pointed out in the above is applicable to all animals, from a lion down to the smallest mouse. Animals of large description require a frame-work suited to their dimensions. These will be pointed out in their order.

A. B. B.

The muscles of the face must be imitated as correctly as possible by stuffing in cotton at the opening of the eyes, as also at the mouth, ears and nostrils. The next care is the insertion of the eyes, which must be done when the eyelids are yet fresh. Some dexterity and skill are required in this operation, and on it will depend most of the beauty and character of the head. The sockets of the eyes are supplied with a little cement, the eyes put in their place, and the eyelids properly drawn over the eyeballs; but if rage or fear are to be expressed, a considerable portion of the eyeballs must be exposed. Draw the lips together, plug up the nostrils with cotton, well tinctured with arsenical soap, to prevent moths from entering. The same precaution should be adopted with the ears, which with the cat require but little attention in setting.

☞ A canary bird, belonging to Miss Barber, of Windsor, Ontario, died August 30, at the remarkable age of fifteen years and two months.



Fresh Water Sun Fish.

Pomotis vulgaris.

THE common Pond Fish, or, as it is usually called in Canada, the little Sun Fish, is the last, least, and most numerous of the Perches that we propose to notice, having already described the more distinguished members of the same family, the various species of Bass. Our chief American piscatorial authority, Frank Forester, says of this small species, the subject of the accompanying illustration:—"This beautiful little fish has gained its provincial name from the extreme brilliancy of its colours when disporting itself in the sunshine. The numerous spots on its body have procured for it the absurd name of *Pumpkin Seed* in many States, and in Massachusetts it is known as *Bream*. It is valueless as an article of food, and equally so as a bait fish, its acute spines deterring any fish from seizing it. It is, however, a constant object of pursuit to boy and lady anglers.

It has very many varieties, and a wide geographical range, being found from lake Huron, through all the Eastern States, and along the Atlantic coast as far south as Carolina.

Its colour is greenish olive above, with irregular points of red and broader yellow or reddish brown spots disposed in very irregular lines. It is marked also with ranges of brighter spots on the bluish operculum, and on the hinder prolongation of the operculum, a black spot with a bright scarlet margin.

Its body is much compressed, very broad, oval. Scales large and even. Forehead sloping to the snout. Lateral line concurrent with the back. Eyes large, circular, near the facial outline. Nostrils double; mouth small, with very minute, thick-set teeth on the maxillaries, palatines, and vomer.

Its dorsal fin has ten spinous and twelve soft rays; pectorals, twelve soft; ventrals, one spine and five soft rays; anal, three spinous and five soft; caudal, seventeen soft rays.

There is another well-defined species, the Black-eared Pond-fish (*Pomolis appendix*), which is distinguished by a large lobe-like black prolongation of the upper posterior angle of the operculum.

TWO SERPENTS AND A CAT: A SINGULAR CASE.—The *Messenger Algerien* relates the following curious story:—"A very singular occurrence took place in the warehouse of the Messageries Impériales at Stora. A large case containing two serpents, directed from Batna to the superintendent of the Zoological Gardens in Marseilles, was deposited in the warehouse for shipment. Whilst there a cat, ignorant of what the case contained, got into it. No sooner had it done so than the reptiles sprang at it with the rapidity of an arrow, and squeezed it to death in their immense coils. They then relaxed their hold, and commenced the process of swallowing. The male serpent seized the dead cat by the head end, the female swallowing the tail end. It is well known that when serpents take into their mouth a substance of a certain size, the conformation of the teeth and jaws is such that they cannot let go their hold. In the present case both snakes were thus brought face to face, the process of deglutition was arrested, and it became doubtful how the matter would end. At length the female snake made a desperate effort to swallow the other, and in doing so was choked." In corroboration of the above facts the animals have been preserved in spirits of wine. The directors of the Zoological Garden of Marseilles are going to bring an action against the Messageries Company for the loss of the serpents, whilst the owner of the cat demands that its skin at least should be given up to him as a matter of curiosity.—*Zoologist.*

WILD DUCKS.—Since the rigid enforcement of the game laws, the inlets and marshes of Burlington Bay are swarming with wild ducks, and owners of private marsh property are encouraged to form preserves. The Hamilton *Times* says that Mr. Wm. Gage, whose locality is well known to sportsmen, on one of the inlets of the bay, has about 300 acres of marsh land bordering his farm, which he is about to convert into a tempting resort for game, by seeding down a considerable portion with the wild rice, having procured a supply of 600 lbs. at no small expense. The grain springs up from the water, and the heads have something of the appearance of oats, though much longer, the kernel being black in colour. It grows luxuriantly, and when once seeded, rapidly spreads over the adjacent marshes.

Stock Department.

The Winter Coat of Horses.

HAIRS and all strictly analogous formations are periodically produced, increase by continuous deposition of fresh matter at the base, and are at length shed, and replaced by a new, and precisely similar growth. When this happens simultaneously all over the skin, the whole coat is changed. The bird moults and comes forth with new and brilliant plumage, and the quadruped casts off its old covering, and acquires a new, fine and glossy garment. These changes are so timed, moreover, as to correspond to the varying temperature of the seasons. The fine short hairs, when first formed, composing a comparatively cool covering for the summer heat, become, by the advent of winter, when they have acquired their full length, a warm and sometimes a shaggy coat, well adapted to defend the body against the rigours of this period of the year. In the horse, and especially in those that are natives of such a climate as ours, this change in the coat is very marked. The increased warmth of the winter covering is ordinarily set off, as it were, by a less glossy appearance. This is partly obviated by the practice of blanketing, whereby the moisture of the skin and an abundant secretion of its natural oils are promoted. The extra artificial covering is also in most cases advantageous as a fit and grateful protection to the animal, in the peculiar circumstances attending domestication and the service of man, against the extreme severity of our winters. In this climate, and with such stables as are found in most farm steadings, the blanket is of essential service, if it is properly employed; but too often it is irregularly used, and serious mischief results. The blanket should not be used upon a horse at all in the winter, unless it is used faithfully. The great trouble in its use arises in this way: When a team has been driven a few miles to market, or the same distance for pleasure, blankets or robes are put on; but when drawing logs to the saw-mill, or doing other heavy work, they are made to haul large loads a mile or two, and return at a brisk trot, then stand unblanketed while another load is being put on. Or perhaps while driving upon the road—sleighing good, speed high—a friend is met and half an hour spent in talking; the horses cool suddenly, take cold, and the owner wonders how it happened. By such inconsiderate treatment more harm results in the use of the extra clothing than if it were omitted altogether. With due care, nevertheless, it is of essential service in the trying winters of Canada.

While the additional covering seems the consistent supplement of the warmer natural coat, it is somewhat strange that the practice of clipping or singeing the hair, before the advent of winter, so as to reduce the protection of the skin against the cold to its very minimum, should find many strenuous advocates. We do not think the custom adapted to this climate, though in the milder and moister atmosphere of England it may be really beneficial. The English hunter, and even, at times, the roadster, are called upon to make violent exertions, which will necessarily excite a profuse perspiration. If in this condition, with the natural thick winter coat of hair, the animal is brought into a warm stable, it will be a long time before the coat will become dry, and the horse is very apt to take cold, from long standing with a wet skin. The clipped coat obviates this danger, saves the groom a vast amount of trouble, gives the animal a degree of life and sprightliness very agreeable to the rider, and apparently exhilarating to the horse, for the same reason that a human being if turned out into the cold with scarcely any covering would be forced to "step lively", in order to keep up the circulation of the blood. To our taste, the practice even in England is no improvement as regards appearance; we prefer nature's finish to man's fantastic docking and shaping. But tastes differ, and fancy in horseflesh is not guided by artistic rules. In this climate, however, on the ground of the severe cold and the sudden and extreme changes of temperature, we cannot think the practice in question either safe or judicious.

"DUCHESS 97th."—The Property of M. A. COCHRANE, Esq., Compton, Quebec.

"Duchess 97th."

WE have much pleasure in presenting our readers with a life-like representation of "Duchess 97th," the costliest Short Horn importation ever made into this country. When Mr. Cochrane brought "Rosedale" to Canada, he placed on our soil the finest known specimen of the Booth family of Short Horns, and "Duchess 97th" is not a whit her inferior as a representative of the Bates family. The story of her purchase, voyage, and arrival has already been told in our columns, so that we need do no more at present than supply her picture and her pedigree. It is a source of pride to all stock men in this country that we possess these choice animals, and Mr. Cochrane has universal good wishes that he may find his large outlay a profitable investment.

PEDIGREE.

"DUCHESS 97TH," Red. Calved March 27th, 1867. Bred by Capt. Gunter, Wetherby Grange, Yorkshire; got by "3rd Duke of Wharfdale," 21619, Roan, bred by Capt. Gunter.

Oldest Horse.

PERHAPS the oldest horse in Ontario is owned by M. Yoder, of Springfield, Elgin County. Old "Jerry" was bought at Mitchell's Corners (now Aurora), twenty years ago. He was sold at that time for an old horse. Twenty-five years ago he was a dashing roadster on Yonge St. He is no doubt now over thirty, and as fat, plump, and handsome as a four year old colt; will not bear the least touch of the whip, and is as shy and notional as he was at his prime. If this is noticed by anyone around Aurora who remembers the horse, will he please send his exact age to the CANADA FARMER, as no doubt many would like to know the age a horse may live to with proper care, and be useful.

Would it not be well to have high prizes at Agricultural fairs for the best old horses? Any one can have a good colt, but it is only a good, kind horseman that can show a sound, active old horse. We see many horses at twelve that are old, prematurely old, every joint out of place, and the owners will boast of heavy loads drawn and long drives.

Old "Jerry" may not be the oldest horse in Ontario, but he would be matched for strength, roundness of form and mettle against any horse over twenty-five in the New Dominion.

☞ The Merino ram, Golden Fleece, owned by Messrs. Mason & French, of New Haven, Vt., recently died of lung fever, or pneumonia. He was valued at $10,000.

☞ The Iowa *Homestead* has an article designed to show that "the extra large breeds of swine are not so valuable for general use as the medium weights."

Veteriuary Department.

Colic in Horses.

Colic is a frequent complaint amongst horses during the fall season of the year, and farm horses are exceedingly liable to attacks of this very painful disease. At this period a common cause is the sudden change in the state of the temperature; a cold, raw day being a prolific cause of the disorder. It is also produced by turning horses out to grass at night, and giving them, when taken up in the morning, a large feed of oats, and immediately afterwards putting them to rapid or heavy work. It is also brought on by allowing an animal to drink freely of cold water when he is in a heated state. Colic occurs in two forms. When the muscular coat of the intestines is spasmodically contracted, it is known as spasmodic colic. When the bowels are distended with gas, it is called flatulent colic. The former is most frequently met with, and the symptoms are well marked. The horse is suddenly seized with excessive pain: he becomes uneasy, stamping with his feet, and looking round his flanks; all at once he will throw himself down, and attempt to roll over and balance himself on his back; this position seems to give the greatest amount of relief; he will frequently break out in a profuse perspiration. In a short time the paroxysm will pass off, and he will immediately get upon his feet again. But before long the spasms will again return, and perhaps with increased violence, when he will throw himself to the ground and roll wildly about as before. During the period of quietude between the paroxyms, the pulse in many instances will be little altered, and over the legs and ears are of a natural heat. When the attack is the result of any debilitating influence, as exposure to cold or hard driving, the pulse is quick and weak, and the ears and legs are extremely cold. Spasmodic cholic, although a very painful affection, is generally of short duration, and by no means a fatal complaint. When it terminates favourably the painful symptoms become less severe, and the interval of quietude is much longer. If an unfavourable course of the complaint occurs, the griping pains increase in frequency, and the animal rolls frantically about, sweat pours off him in streams, and the pain becomes almost continuous, and inflammation of the intestines sets in, which speedily terminates in death. Death may also occur from the violent spasmodic contractions. In the treatment of this disease, the patient should be placed where he has plenty of room to roll about as he chooses; nature tells him the position which gives relief. Frequently poor animals are subjected to very harsh treatment with the view of keeping them upon their feet; the whip is freely applied and they are kept trotting about, which, instead of relieving, has a tendency to aggravate the symptoms, and we have no hesitation in saying that many valuable animals are lost from this absurd and cruel practice. There are many medicines used which have an excellent effect in giving speedy relief. One of the best is one to two ounces of the tincture of opium, given in four to six ounces of water or linseed oil. If no relief follows in one hour, half the dose should be repeated. Injection of soap and water should be given every half hour, and the abdomen well hand-rubbed. When the pain is very severe, hot cloths applied to the belly have a very good effect. Except in cases where inflammation of the bowels is likely to take place, blood-letting is not required. After a severe attack it is always advisable to allow the horse a day's rest.

Scratches on Horses.—A correspondent of the *Country Gentleman* sends that journal the following recipe, which he pronounces "the best medicine that can be made" for the ailment above-named:

4 oz. ointment of rosin; ½ oz. finely ground verdigris; 2 oz. turpentine; ½ oz. oil of origanum; ½ oz. tincture of iodine; 1½ lb mutton tallow. Mix all well.

Wash the foot clean with castile soap and soft water, and apply the ointment after the foot becomes dry. Once a day will be sufficient to apply the ointment.

The Dairy.

Dairymen's Association.

The Secretary of the American Dairymen's Association has sent out the following, which is worthy the attention of dairymen:—

"The time has now arrived when dairymen should be preparing for the next annual convention of this Society. They are now in the midst of cheese making, and are favorably situated for experiment and tests; for proving or disproving the various theories relating to the business; for searching for the causes of the troubles which the practical cheese-maker so often encounters. For instance, there is an almost universal complaint this season, of the floating curd. Careful observation on the part of many dairymen in various sections, when brought together and compared at the convention, may lead to a solution of this difficulty, by pointing out the cause, and thus indicating the remedy; and so respecting other troubles.

Besides, the subjects under discussion at the meeting last January were by no means exhausted, and it is known that scores of factories are testing the value of the suggestions then made regarding curd, milk, two days' pressure, etc. Let us have the result of these tests.

It would add greatly to the interest of the convention, if members—practical dairymen—would take a more prominent part in the meetings, coming with short and carefully prepared papers on subjects connected with milk and cheese, giving results of experiments and the conclusions drawn from them, of new theories and practices respecting cheese-making, or any of the details of the process, and the reasons and observations which have induced the change.

Another valuable feature might be added in the introduction to the notice of the convention of samples of cheese, shown for their style, manner of manufacture, or for other reasons, not with a view to competition, but that this demonstration may be made of the value of the experiments of which the cheese shown is the result.

Communications from dairymen and others upon subjects relating to this matter, or making suggestions respecting the next annual meeting, will receive prompt attention.

Let members begin at once to prepare themselves to add to the interest and value of the convention of January, 1869."

New Milk Cooler.

A milk cooler, exhibited at the Herkimor County Fair, deserves special notice. On first inspection it might be mistaken for an ice cream freezer, but after a closer examination and a little explanation from the stranger who was exhibiting it, it was found to be a device for cooling milk as it is drawn from the cow. The construction being novel, and of some interest to dairymen, we will attempt a brief description for the benefit of our readers. The milk, as it is poured into it, passes in a thin circular sheet, about the thickness of wrapping paper, for a distance of about three feet, between two thin metallic surfaces, over which cold water is constantly passing. By this means the animal heat is entirely removed, and the milk reduced, gradually but immediately, to any degree of temperature desired. A thermometer being attached to the machine, having its bulb immersed in the cooled milk, enables the operator to watch and control the process. The milk, after being cooled, is collected together and passed out through a tube, to which a faucet is attached, into a pail or can. It is claimed for this little affair, which is called the "Empire Milk Cooler," and which a child can carry in his hand, that it will cool milk as fast as four or five men can milk. Gardner B. Weeks, the Secretary of the American Dairymen's Association, has examined it, and recommends it for general use "in private dairies, as well adapted to put the milk in admirable condition for sending to the cheese factory or market." The machine can be readily taken apart and cleaned, with the greatest facility. We hope an arrangement will be made with some of our manufacturers of dairy utensils, to enable our dairymen to test the utility of this cheap and simple device. If one-half which is claimed for it is true, it will indeed be a valuable accession to the dairy interest. It took the first premium at the State Fair. The inventor is Dr. M. F. Potter, of Kaneville, Illinois.—*Am. Exchange.*

☞ The London dairymen have decided that the most profitable cows are graded short horns, not because they give more milk, but because when past milking they make most beef.

Poultry Yard.

Pigeons.

To the Editor of The Canada Farmer:

Sir,—A few remarks on fancy pigeons, in continuation of the letter which appeared in the Canada Farmer of September 15th, may interest some of your readers. Fantails are perhaps the most numerous of any fancy pigeons in Canada, and are sometimes pretty good; but they are far behind the "Side View" in Tegetmeier's Fantail. Many have tufts, but want that shape and fineness of neck so desirable. I have never seen any with the carriage up to the English standard.

The best fancy pigeons in Canada are the Trumpeters, although here they are called Drummers. They are as a class deficient in size, but the moustache and feathering are good. They are chiefly whole-colored. The Black Mottled are considered the best; but I remember in the year 1830, seeing at Mr. Warner's, of Hoddesdon, Hertfordshire, England, what I have never seen since, a large flight of these birds, which were white, with little black crescents all over their plumage. They were very similar in color &c., to the picture given in Mr. Eaton's work, but, if possible, more uniformly marked. The effect of this plumage was very pretty and peculiar.

Turbits are scarce in Canada; some few specimens are good, but there are not many, although from the markings of the mongrels in the streets there appears to be a very general tendency to Turbit shoulders.

Owl Pigeons in Canada are represented by one pair. There are some breeds called such, but very inferior specimens.

Runts are unknown. There are plenty of mongrels, but no true Runts.

Of the German Toys I have seen attempts, but nothing very striking, and of course they are very scarce.

I was almost forgetting the "Barb." Mr. Johnson, of London, exhibited a good pair at the Ontario Show. These are the only specimens I have met with of any merit.

I think I have mentioned all the varieties I have met with. They are all decidedly below par; but as the utility of them is questionable, except as an amusement, it is perhaps no wonder that they should be scarce in a young country like this. Nevertheless, as the Societies are in their annual exhibitions offering premiums for the best of the different varieties, I can but hope that the specimens will deserve the prizes awarded.

F. C. HASSARD.

Toronto, October 20, 1868.

Ontario Poultry Association.

The first meeting of the season was held on Friday evening, Oct. 16th, in the Agricultural Hall, Yonge Street. There was a fair attendance of members. After the transaction of some routine business, and the election of several new members, the subject of a Fall Show was discussed. It was urged by several members that the holding of two poultry shows in the year was too much, and that the efforts of the society should be concentrated in one annual exhibition, to be held either in the spring or fall, as would be thought most suitable to exhibitors, and advantageous to the public. As the subject was one on which a fuller expression of opinion from exhibitors was deemed desirable, no final action was taken; it was, however, determined on holding a fall show on the 25th of November next, open to the entry of birds of members of the Association only. As this exhibition is not intended for competition, but merely to give fanciers the opportunity of showing and comparing their birds, and of selling and making purchases if desired, no prizes will be awarded. It is understood that several members of the Association had imported some choice poultry from England and the continent of Europe during the summer, and several more specimens are on the way here. The praiseworthy efforts of the Poultry Association deserve every encouragement; and this contemplated exhibition without prizes should be especially appreciated by the public, as affording an opportunity of improving stock from the progeny of choice imported birds at prices much below the original cost to the importers. We trust the project will be carried out and prove successful. Intending exhibitors should apprize the Secretary of their purpose before the close of the week, as the 25th of the month has been fixed upon as the date, on or before which all applications for pens should be sent in; and the holding of the show will depend on the number of specimens that may be expected. The final decision on this matter will probably be made on Monday, the 9th, when the Association hold their next meeting.

Duty on Imported Poultry.

A number of valuable importations of poultry from Great Britain and the continent of Europe have recently been introduced into this country at considerable cost by enterprising individuals, who deserve all possible encouragement in their efforts. It is the wise policy of many public bodies in this country, and in general of the Government of the Dominion, to foster in various ways the improvement of our live stock by importations from the old country. The Provincial and other agricultural associations double the amount of premium gained by any imported animal, and the Government have taken off the duty on most classes of live stock imported for the improvement of the breed; but hitherto the class of poultry has not shared in this exemption. The subject was brought up at the last meeting of the Ontario Poultry Association, and the Secretary was requested to communicate with the Commissioner of Customs, and ascertain how the law stood in this matter; for, naturally believing that the same regulation which applied to the importation of cattle extended to poultry, some gentlemen had declined to pay the duty on their imported fowls. The Secretary accordingly wrote to the Commissioner of Customs at Ottawa, and received the following reply:

"In reply to your letter of the 17th instant, I beg leave to inform you that the Tariff sanctioned by Parliament on the 22nd May last (31 Vict. cap. 44) is the present law governing duties and exemptions on importations into Canada. The Act referred to supersedes all previous rules and orders at variance with its provisions, and the free list in the schedule to that Act not containing any exemption in favour of the importation of poultry for the improvement of the breed, the department has no power to create one, and the article is therefore dutiable as non-enumerated.

I have the honor to be, Sir,
Your obedient servant,
R. S. M. BOUCHETTE."

Such being the case, the Commissioner of Customs has of course no option in the matter; but we believe the omission in the law as it stands should be remedied, and now that the matter has been brought under notice, we trust the Department will seek at the next meeting of Parliament to have the class of poultry put on the same footing as other stock; for though not equal in importance to the nobler animals, they should not be overlooked, and the importation of fresh specimens from Europe involves in itself a considerable amount of trouble and expense, which should not be increased by the additional burden of a Government impost.

☞ A Parisian speculator sent a large number of carrier pigeons to Lisbon, to replace the telegraph, when all communication with Spain was interrupted

Entomology.

Cockroaches.

These disgusting creatures, which swarm at night in the kitchens and cellars of houses in towns, are happily seldom or ever seen in the country, thus lending an additional though negative charm to farm life. Many nervous people and cleanly housewives detest them—indeed to such an extent that they would gladly exchange the comforts and conveniences of town life *with* cockroaches, for the, to them, more dull existence in the country *without* cockroaches. To be sure we have them in the country, but then our rural species are only found under stones and the bark of old stumps, and very rarely, if ever, in houses. The domestic species, like many of our most noxious insects, is an imported pest, and not a native of this country; it is supposed to have come from the East Indies originally, by the aid of commerce, and thus to have spread all over Europe in recent times; thence it came to the seaboard towns of America, and now it is to be found in all our large towns and cities, even a thousand miles from the sea. Its flat form enabling it to creep under the hoops of barrels and into the crevices of trunks and packing cases, as well as its secret nocturnal habits, causes it to be carried about without notice, and renders easy its establishment of colonies all over the world. Though commonly called a "black beetle," it is not a beetle at all, but belongs to the soft-bodied, straight-winged order of insects (*orthoptera*), which includes also crickets, grasshoppers, and locusts; all of them have their under wings, when not in use, beautifully folded up like a fan, in long straight plaits over their back; and they also differ from beetles in undergoing no complete transformation in coming to maturity, the larvæ being generally only distinguished from the adults by the absence of wings and variableness of size, and the pupæ (unlike those of most orders of insects which are inactive during this stage) by their rudimentary scale-like wings. Our common species is about an inch long, and of a dark brown colour; in the eyes of most people it is a sufficiently repulsive object, but what would our lady friends say if they found their larders and pantries infested by the kind that swarms in the tropics, whose wings expand six inches, and whose bodies and appetites are large in proportion! We have in our collection a specimen brought us from Mexico, whose wings expand five and a half inches, while its body is two and a half inches long and an inch broad; with the exception of breadth of wing, it is as large as the immense emperor moth that we figured in our last number. Fancy such huge beasts flapping about your kitchens and trailing their loathsome bodies over your various household stores, and then thank Heaven that you live in Canada, and not in the tropics! They are said to devour all kinds of victuals, dressed or undressed, and to damage all sorts of clothing, leather, books, paper, &c., which, if they do not destroy, they at least soil with their filthiness. They swarm by myriads in old houses, making every part filthy beyond description. They have also the power of making a sharp knocking with the knuckle upon the wainscoting, whence one species is called the drummer in the West Indies; and this they keep up replying to each other through the night, to the great annoyance of those who are trying to sleep; those who do sleep are even said to be sometimes attacked by them, and they will also eat the extremities of the dead. Thus it appears that there is no respite from them at night, asleep or awake; dead or alive, they give no peace!

The common household species in this country, though bad enough, is of course not to be compared to the foregoing. As is well known, it is nocturnal in its habits, hiding itself during the day in holes and crevices, under the skirting boards of rooms, &c.; it is very fond of heat, being generally found in the greatest numbers near stoves and furnaces, and especially about bakers' ovens, where they have the additional attraction of a constant supply of food. It eats flour, bread, meat, in fact all kinds of provisions, and has a particular relish for anything greasy or oily; it is fond also of the blacking on boots, and will sometimes eat leather and all. If any one wants to know what cockroaches look like, all he has to do is to go at midnight with a lighted candle or lamp, and suddenly enter the down-stairs kitchen of some friend's house in town; he will see these disgusting creatures scuttling off in every direction over the tables and floor, and will probably learn quite enough about their appearance in a very few minutes.

How to get rid of these creatures, is the next question. A capital trap for them may be made with a small wooden box, having a circular hole at the top fitted with a glass rim, out of which it is impossible for them to escape. It should be nightly baited, and the contents thrown the next morning into scalding water. Various poisons are also used with success; Dr. Harris mentions the following:—Mix together a table-spoonful of red lead and of Indian meal, with molasses enough to make a thick batter, and place the mixture at night on a plate or piece of board in the closets or on the *hearths* frequented by them. They will eat it, and become poisoned thereby. The dose is to be repeated for several nights in succession. Another mode is to mix one teaspoonful of powdered arsenic with a table-spoonful of mashed potato, and crumble one-third of it every night, at bed-time, about the kitchen hearth, or where these insects will find and devour it. As both these preparations are very poisonous, great care should be taken in the use of them and of any portions that may be left.

Mosquitoes in England.—The tropical heat of last July, which prevailed in Northern Europe as well as in this country, appears to have rendered the gnats of England peculiarly rabid, as we may judge from the following account taken from an old country paper:—

"A large number of girls and boys employed in the East Laboratory, or marsh portion of Woolwich Arsenal, have been disabled by the mosquitoes, the swelling and irritation in some cases assuming an alarming and dangerous appearance. The stings are treated at the Arsenal Infirmary by an alkaline lotion of common soda and water, the poison emitted being an acrid acid. Several entomologists have visited Woolwich, and they all agree that the insects are the *Culex pipiens* of the gnat genus, common to the watery and marshy places of all countries, but deriving additional vigour and ferocity from a warm and moist condition of the atmosphere. Legions of these English Mosquito larvæ can be seen in the stagnant ditches at North Woolwich and the marshes at Plumstead. They thrust a sharp and strong proboscis into the soft skin, preference being given to females and children. Though they become more blood-thirsty and venemous in hot weather, some experiments made with them in the arsenal prove that they can resist any degree of cold."

A few years ago we remember an English medical friend of ours, who came out to settle in the backwoods of this country, was obliged shortly after his arrival to place his arm in a sling, on account of a single mosquito bite: he soon, however, became more accustomed to them.

Water-Snakes.—We are much obliged to "Zebra" for the interesting specimens of these curious creatures that he has allowed us to retain. We purpose preserving them in alcohol. His duplicate specimens, we should think, might be kept alive for some time by frequently changing the water in which they live. It would be an interesting experiment to present the young ones with a grasshopper, cricket, or other insect, and observe whether they would attack it or not. Our correspondent states that he finds them an unerring weather-glass, as they poise themselves at any distance between top and bottom of the water in the vessel; we have observed the same thing with leeches, which we have kept for some months in water, and always noticed that they varied their position in accordance with the greater or less density of the atmosphere.

Correspondence.

Winter Barley—Crops in Hastings, &c.

To the Editor of THE CANADA FARMER:

SIR,—I am pleased to hear that you have sent for some of the wheat advertised by Mr. Deitz, and shall be interested in learning how it succeeds with you.

I see by his circular that he advertises a variety of winter barley for sale. Would it not be worthy of experiment? Some varieties of it must be very hardy to grow and mature in latitudes where, if I am informed correctly, other cereals do not flourish. In high, loamy land, too light for the spring barley, for the short time it has to grow, it would, perhaps, be valuable. Another advantage would be its ripening earlier, so that a crop of buckwheat or turnips could be sown after it. It weighs more to the bushel than spring barley, and is therefore more profitable. How can a straw-cutter be used to best advantage in economizing fodder? Would it pay to cut up corn-stalks for cattle? If you would favour us with an article on the use of it, it would be of interest. Our crops here are rather light, especially spring grain. Many fields of peas were not harvested—some yielded nothing but straw, never blossomed. Such kinds as grow very quickly would be best adapted for such a season. Farmers have sown more fall grain than usual, I think. On stiff tenacious clays, the growth of fall grain should be encouraged. Clover crops were benefited no much by a liberal dressing of plaster and the early rains, that they bade defiance to the drought, and a large crop was obtained in good order. The second crop was rather poor, and not worth saving for seed in many places. Potatoes are very much benefited by the late rains; but other root crops are poor. I sowed turnips twice without success; but I have a few rows of fine carrots. I think other roots are surer than turnips, mangold wurzel, kohl rabi or carrots. There will not be a large crop of fruit hereabouts. Apples, in old orchards especially, are small, and bear evidence of the severity of the drought; but young trees, properly mulched and attended, bear fine large apples. Is not fresh manure injurious to young apple trees? What is the best dressing? We have a green-gauge tree on our place, apparently very thrifty, but it never bears. What would be the best way to make it fruitful? The Web Fall Caterpillars were very numerous on the trees here, not only on the apple. JOHN LEBOUTILLIER.

Sidney, Sept., 1868.

NOTE BY ED. C. F.—We have to apologise to our correspondent for the late appearance of the above letter. The pressure of Exhibition and other matter has prevented an earlier insertion. With regard to the use of corn-stalks for fodder, we can say from personal experience that, cut with the straw-cutter, and mixed with other food, they are useful and economical. In Illinois we fed them both in this way, using horse power to the straw-cutter, and also by the ruder and more common method of turning stock into the fields after the corn crop was gathered. The feed contributed its full share to keep our cattle in excellent condition. We believe barnyard manure and ashes a good dressing for orchards. Other miscellaneous queries shall receive attention as soon as possible.

A LADY writing from Hull Township has our best thanks for her pleasant communication, which is, however, too late for more than this acknowledgment in our present issue. We reserve it for the earliest opportunity of publication.

WEANING COLTS.—An inquirer from Quebec, over the signature "Gosford," writes:—"If any of your correspondents practically acquainted with a good way of weaning colts would give the benefit of his experience through your columns, he would confer a great favour."

We hope some experienced farmer or breeder will respond to the above.

ALDERS.—PAINTS.—A correspondent sends us the following brace of enquiries:—"Please inform me, through the medium of your paper, the easiest and most effectual method of eradicating the 'Alder bush' so often found growing on our streets, uncultivated fields and fence corners—also, the different ingredients and proportions used for painting agricultural implements and waggons. Colours, red, blue, green, yellow, and brown."

ANS.—The Alder flourishes on wet land and river sides. We never saw them in the *streets*. Grubbing and draining will destroy them. With regard to the second query, the proportions of oil and solid material to produce the requisite consistence will soon be ascertained by experience. For the colours mentioned the following ingredients are required:—Red, Venetian red; blue, Prussian blue and a little white lead; green, Brunswick green; yellow, chrome yellow and a little white lead; brown, black, with a little Venetian red.

DEEP PLOUGHING.—A subscriber, whose example we highly commend, sends us the following communication and enquiry:—"I have just finished ploughing a field with three horses. I ploughed it about twelve inches deep. The soil is a stiff clay, and it is very hard in the bottom. Would you be kind enough to inform me whether I could cultivate such land any deeper? Would it be best to plough it again this fall, or plough it in the spring?"

In reference to the deep ploughing, our correspondent does not inform us what sort of plough he used. It is not well, especially in cold clay, to turn *up* to the surface too much new soil at a time, though it can hardly be loosened too deeply. The next ploughing would be most advantageous in the spring, or might perhaps be dispensed with by the use of a good cultivator. Our correspondent is in the right track, and will no doubt see the benefit of his trouble in augmented crops. An excellent method of deep cultivation is to follow in the furrows made by the first plough with a subsoil plough that shall loosen and stir the ground to the depth of several additional inches without bringing fresh soil to the surface.

The Canada Farmer.

TORONTO, CANADA, NOVEMBER 2, 1868.

Westward Emigration.

THERE is no denying the fact that a large proportion of the fresh arrivals of emigrants from the Old Country pass through Canada to settle in the Western States. We continually meet in the daily papers such announcements as the following:—"A train of five hundred emigrants passed through the city to-day, most of whom were bound for Wisconsin, Illinois, or Iowa." Of these a large number may be Germans or Norwegians, but there is no doubt that, even from British ports, a considerable proportion of those who cross the Atlantic and land on our shores do not take up their permanent abode with us, have not come out with a view of instituting any comparison of the relative advantages of Canada and the States, but left home with the fixed intention of settling in the fertile lands of the adjacent Republic, and using this country merely as the readiest highway to the West, scarcely even look upon us, and "pass by on the other side." It would occupy far more space than the limits of an article in an agricultural journal to discuss fully the reasons or the merits of this widespread preference, but it may not be amiss briefly to notice the important subject, and show why we do not think that even the most favoured regions of the West possess any overwhelming advantages, as a field for emigration, over the unoccupied and inviting portions of our own Dominion.

In addressing British subjects it is hardly necessary to say that there is nothing in the government or institutions of the United States that will secure a greater amount of personal freedom and social rights than will be found under British or Canadian rule. All that is best and noblest in the constitution and laws of the "Great Republic" had its origin in the spirit and institutions of the mother country: and there is no people in the world who enjoy more true liberty than the subjects of Great Britain. Nay, more; we are fully convinced that in this respect there is no nation under the sun can boast of equal advantages. No one, now-a-days, will exchange the British dominions for any land on the face of the earth, to secure greater freedom than is enjoyed throughout the whole extent of the empire.

If it is not the government of the United States, is it the climate of the country that gives the Western portion any superiority over ours? In this respect, we believe the advantage is with us. Of course over so vast a territory there is great diversity of climate; but comparing our own with that of Wisconsin, we perceive a close similarity, while in many respects we prefer the climate of Canada to that of Michigan, Central and Northern Illinois, or Iowa,—the portions of the West with which we are best acquainted. In these States the cold is more severe than it is with us, the heat of summer is more intense and trying, and the changes of temperature are more sudden and extreme. The snow, which generally for a long season covers the face of the earth in Canada, is also a great advantage, both as a protection to winter crops, and as affording facilities of traffic and travel. In this country we are also comparatively free from those intermittent and other fevers that prevail to so serious an extent over a large portion of the Western States. Most people who have lived, as we have done, in both countries, will give the preference to Canada, as regards climate.

Granting that the broad West cannot boast of a finer climate than our own, it may be claimed that the soil of the region is superior. We will acknowledge that it is more uniformly of excellent quality. The prairie land especially cannot be surpassed in richness and fertility; and for the growth of the staple crop of the country, Indian corn, both soil and climate undoubtedly surpass the very best districts of Canada. But this is not the case in regard to other crops. The cereals flourish best with us; and the average yield of wheat especially is larger, per acre, throughout the whole of the wheat-growing region of the Dominion, than anywhere in the States. The place of corn, too, as winter food for stock, is well supplied by roots, which find a more congenial soil here than either in the South or West. Many portions of this country are also as well adapted for the growth of all kinds of fruit as any part of the West.

With regard to the profits of agricultural produce, we are nearer the seaboard, and of course nearer the markets, than our neighbours, and command, therefore, a higher price for all we can raise. This is a most important consideration, and would counter balance any presumed advantage of either richer soil or cheaper land. The same remark applies to the profits of live stock. If we have no unoccupied prairies for free pasture, we can sell at a price that will amply repay the additional cost of raising; and we can point to the success of our principal breeders, and the excellence of their stock, in evidence of the profitable field which Canada offers for this branch of agriculture.

There is again another point in which we have the advantage; namely, the cost of living. The heavy taxation and the unsettled state of the currency, consequent on the late unhappy war, have so depreciated the value of American money and increased the price of all articles of clothing and most of the necessaries of life, that the United States has become notoriously a dear place to live in. Many have been tempted by the deceptive accounts of high wages in the States, forgetting to make allowance for the depreciated currency, have left Canada to try their fortunes on the other side, have been woefully disappointed, and after a longer or shorter trial have gladly returned to this country, poorer but wiser than when when they left it.

If we allude to another consideration which will have weight chiefly with Englishmen, that is, the sympathy they will meet with here and miss on the other side in regard to their national predilections, we trust we shall give no offence to any right-minded American. It is of the highest importance that friendly and fraternal feelings should be cultivated between neighbours so closely allied, and from personal experience we have every reason to speak well of the frank, kindly, and generous disposition of those Americans with whom we have come into closest contact. During a residence of six years in the west, we do not remember hearing a single remark calculated to wound our national partialities or give offence to our patriotism. But while we gladly give this testimony in regard to our personal intercourse with the people, we must be allowed to make exception to the tone of too large a portion of the American press, and record our conviction that a loyal Englishman would be more at home in Canada than in the land of the *New York Tribune* and other organs and abettors of Fenianism, the maddest and most wicked phase of anti-British mania. Moreover, it is not to be denied that a reckless and lawless spirit is too prevalent in some portions of the country; though this remark applies less to the West than to the South, where Liberty is so very rampant that a trusty revolver is a necessary weapon of self-defence against her vagaries.

No doubt a large amount of the popularity enjoyed by western lands, and the consequent influx of emigration, is due to the liberal policy of the American Government in the free grants of land and the general encouragement given to emigrants. Much also is due to the filial and fraternal spirit that induces the Irish, Germans, Swedes, and Norwegians who have found a home on this side the Atlantic to expend their first earnings in assisting other members of their families from the fatherland to join them in their newly adopted country. The whole subject is one of great and pressing importance, demanding the serious consideration and the prompt and liberal action of the Canadian Government. Much may also be done by disseminating correct information respecting the resources and prospects of this country, not only in England, but also in those parts of the European continent whence the stream of trans-Atlantic emigration chiefly flows. New railroads are projected, now territory will be opened up, and many fresh inducements are yearly growing out of the progress of our Dominion that should bring a large accession of population to this country from the struggling classes at home. We frankly avow our belief that as there is no portion of the British colonies so easy of access, there is also none that offers a better prospect to the emigrant than this Dominion of Canada; and we have yet vast tracts of territory inviting occupation, that are as eligible for settlement as any district within the limits of the United States.

Cattle Disease Convention.

WE gave some account in our last issue of a meeting held at Rochester, N. Y., during the State Fair, in reference to the Texan cattle disease, at which it was unanimously resolved to take steps toward summoning a Convention with a view to uniformity of legislation in the several States of the American Union, and in the Dominion of Canada, both in regard to the disease now raging, and the regulation of matters connected with the transportation of cattle. The Cattle Commissioners of the State of New York have issued a circular calling such a Convention, and we have pleasure in giving it an insertion in our columns. We have been permitted to see a private letter from one of the New York Commissioners, the Hon. J. S. Gould, to the Hon. D. Christie, in which that gentleman states that the Texan disease is still rife,—that it appears to be most insidious in some of its characteristics, and that positive proof has been obtained that it may be and has been transmitted from native cattle to native cattle, that have never been in contact with the Texans. Mr. Gould thinks we have made a mistake in relaxing the stringency of our regulations, and says that there is an absence of strict inspection, so much so that an ox with an enormous cancer on his face went through to Buffalo the other day. The circular is as follows:

ALBANY, October 13, 1868.

DEAR SIR:—In view of the ravages of the disease known as the Texas Fever among cattle, and the inadequacy of the laws enacted by the several States for the repression of this and other kindred diseases, and the conflicting provisions of these laws, which have been disclosed since this disease has been prevalent, a general desire has been felt and expressed by farmers, drovers, and the consumers of meat in several States, that a wise and efficient system of legislation should be adopted for the repression and prevention of this and other similar diseases in the several States, so that the laws should be harmonious and adapted to mutual protection. And it has been believed by nearly every one that has expressed an opinion upon the subject, that the best mode of effecting this object is by the assembling of a convention of the Cattle Commissioners of the several States interested in the subject, who would represent all the varied interests of the producing and consuming States, and supply all the information necessary for the full elucidation of the subject, and whose duty it should be to prepare a draft of a law which should ensure the most perfect protection to all parties, to be recommended to the several Legislatures for adoption. And the Commissioners of the State of New York having been requested by the Commissioners of several of the States, and of the Dominion of Canada, to take the initiative in calling such convention,

We do, therefore, recommend that a convention be held in the city of Springfield, in the State of Illinois, on Tuesday, the first day of December, 1868, at twelve o'clock noon of said day.

The object of such convention is to consider the pathology, symptomatology and history of the Texas cattle fever and other infectious and contagious diseases to which cattle and other stock are subject, and the best methods of preventing the spread of such diseases with reference to the interests of the producer and consumer, and also to consider the sanitary requirements of the community with reference to the feeding and rest of the animals in transitu, and to the best methods of slaughtering and preparing them for market. The convention will also prepare a draft of a law which shall provide for the accomplishment of these objects, to be submitted to the Legislatures of the States represented therein for adoption. Each State and Province to be represented by three Commissioners. The Cattle Commissioners of the State of Illinois are requested to secure a suitable place of meeting for the convention.

His Excellency, the Governor, is hereby respectfully requested to transmit copies of this call to the Governors of the several States, where such Commissioners are not already appointed, with a request that they would appoint such Commissioners to represent their States in the Convention.

M. R. PATRICK,
L. F. ALLEN,
JOHN STANTON GOULD.

The Nova Scotia Provincial Exhibition.

FROM the accounts that have reached us of the great Agricultural and Industrial Exhibition of Nova Scotia; it appears that the undertaking has proved eminently successful. The Exhibition was open from the 5th to the 10th of October, inclusive, was largely attended, and excited a warm and general interest. We gather, chiefly from the report of a speech delivered on the occasion by Hon. Joseph Howe, that the great feature of the show was the collection of apples, which we are told could not have been surpassed in any part of the world. Of other fruit there was a fine display. There was also a splendid collection of vegetables. The show of stock was creditable. The principal prizes for cattle were taken by agricultural societies. The world-renowned name of Cunard figures also conspicuously in the prize list. The industrial department bore ample testimony to the mechanical skill and enterprise of the Province. The eloquent speech of the Hon. Joseph Howe, in which he expatiated with patriotic pride on the wonderful progress of the Province and the noble character of the people, closed the public proceedings, which appear to have been altogether of a very enthusiastic character. We hope to receive an official account in the next number of the *Nova Scotia Journal of Agriculture*.

Book Notices.

DRAINING FOR PROFIT AND HEALTH. By Geo. E. Waring, Jr., Engineer of the Central Park, New York. Illustrated. New York, Orange Judd & Co: 245 Broadway.

WHETHER viewed in its relation to the profit of farming, or the health of towns and cities, drainage is well worthy of much more attention than it gets either in town or country. The little work above-mentioned is the completest and most practical treatise we have met with on the important subject to which it relates. Within the compass of some 250 pages, it treats of the reasons for draining; how drains act, and how they affect the soil; how to lay out a system of drains; how to make the drains; how to take care of drains and drained land; what draining costs; will it pay; how to make drain tiles; the reclaiming of salt marshes; malarial diseases; house drainage and town sewerage in their relations to the public health. The illustrations, forty-nine in number, make the practical directions very plain; and altogether this is just the book for an intelligent farmer who has resolved to drain, and means to do the work thoroughly while he is about it.

THE PERCHERON HORSE. Translated from the French of Charles Du Huijs, Author of the "Dictionary of the Pure Race;" "Trotters;" "The Horse-Breeder's Guide;" &c. Illustrated. New York Orange Judd & Co., 245 Broadway.

THE breed of horses of whose history, qualities, and characteristics this little work treats, is beginning to attract considerable attention in this country. Four stallions of this class were exhibited at the recent Quebec Provincial Fair, all imported from France within the past two years. We believe they will prove a great acquisition to the farmers of the Dominion, inasmuch as they combine the qualities that are valuable on the farm in a higher degree than any other known breed. Of larger size than the Clydes, being on an average taller and longer, and of scarcely inferior muscular development, they are nevertheless capable of attaining a high rate of speed on the road. Indeed, for moving heavy loads quickly they have no equals, as travellers who have ridden in French diligences and Parisian omnibuses uniformly testify. What the farmer wants is a horse with which he can plough deep, haul a large load, or drive his family to church and market, at something more than a snail's pace. This he has in the Percheron. The work above-named supplies all the desirable information respecting this valuable animal, and we commend it to the attention of the stockmen of Canada.

AMERICAN AGRICULTURAL ANNUAL FOR 1868. AMERICAN HORTICULTURAL ANNUAL FOR 1868.

FOR some reason or other, these publications, issued by Messrs, Judd & Co., of New York, have only recently come into our hands. But they have a permanent rather than transient value, and furnish a large amount of practical information, useful any month in the year, and any year in all time. The *Agricultural Annual* contains, in addition to much other valuable matter, nearly thirty pages of information respecting factory cheese and butter-making, which render it worth many times its cost to any dairyman; while its Horticultural companion is crowded with a miscellany of useful and attractive contents, among which it would be difficult to elect what is of greatest interest and worth, without it be the articles on small fruits and new vegetables. Both publications are beautifully and profusely illustrated.

A FOURTEEN WEEKS' COURSE IN CHEMISTRY. By J. Dorman Steele, A.M., Principal of Elmira Free Academy. New York: A. S. Barnes & Co., 111 and 113 William Street.

THIS publication is meant as a school text book, but is equally suitable for private use. It is intended to teach such as do not expect to become chemists, nor even professional students, a few leading principles and applications of the noble science to which

it relates. The preface states that "unusual importance is given to that practical part of chemical knowledge which affects our every-day life, in the hope of bringing the school-room, the kitchen, the farm, and the shop into closer relationship." This book is likely to give not a few, who study it, a great desire to study more extended treatises, and if it does this only, it will prove a very useful contribution to the cause of popular education. But beside this it will give many a glimpse of the temple of nature, who cannot possibly explore its mysteries, or study its beauties to any great extent.

A Fourteen Weeks' Course in Descriptive Astronomy.

This work, by the same author as that last mentioned, and issued by the same publishing house, is also similar in its plan and purpose, and aims to do in the region of Astronomy what the other work does in the domain of Chemistry. Recent discoveries in astronomical science are particularized in this volume, and the latest information concerning Meteors, Shooting Stars, and the results obtained by the Spectrum Analysis, are likewise given. Star maps form a noticeable feature in this work, enabling the teacher and student to get on without either globes or charts. Although farm operations are not to be guided by moon or stars, yet the farmer may well aspire to know something about

> "The spacious firmament on high,
> With all the blue ethereal sky
> And spangled heavens, a shining frame;"

and here within small compass, and at a trifling cost, may be found a choice store of knowledge in regard to these familiar and attractive objects.

Lessons on Political Economy. By J. T. Champlin, President of Colby University. New York: A. S. Barnes & Co., 111 and 113 William Street.

Let no "loyal Briton" suspect us of Annexation tendencies in noticing this work, for it does not treat of republicanism, or of any other particular form of government, but deals with subjects common to all civilized nations, as will be seen by a glance at the following summary of its contents:—"Wealth, and the means of creating it; value, cost, price; capital, and its forms; labour, its forms and results; division of labour; aid to production from natural agents; stimulants to labour; taxes; profitable and unprofitable labour; business; exchange; money, metallic and paper; banks and banking; credit; finance; interest; land and rent; profit and wages." A very useful book for the farm library.

Violet Keith. An Autobiography. By Mrs. Ross. Montreal: John Lovell, St. Nicholas Street.

This is a Canadian publication, and from the pen of a Canadian authoress. As a native product, we are quite proud of it. It is well written, paints very graphically scenes from real life, and has an air of truth and actuality about it which cannot fail to interest and impress readers of every class. It is a capital book for the fireside and chimney corner, these long, chill nights which November is ushering in. It is wholesome in sentiment, inculcates lessons of true wisdom, and is emphatically a *family* book. It is winning golden opinions from the editorial fraternity, and will doubtless have, as it deserves, a wide sale.

The "Rural American."—The proprietors of this excellent agricultural journal, one of our most valued exchanges, have recently effected several considerable alterations in the conduct of the paper. Some time ago the office of publication was removed to New York City, and the editorial office to the City of New Brunswick, in New Jersey. On the first of October a double number was issued, with the intimation that it would in future be published once a month only, instead of fortnightly, and that its size would be doubled. We think this an improvement. The first monthly number is full of valuable matter, and is an excellent specimen of a practical and interesting journal of agriculture and rural affairs.

Agricultural Intelligence.

Annual Sale at Moreton Lodge Farm, Guelph.

The sale of Mr. F. W. Stone's stock, which came off on the 15th ult., was less extensive than usual, no cattle being offered. The lots consisted of Cotswold and Southdown sheep, and Berkshire pigs. There was a fair attendance of buyers, including a number of prominent stock breeders from various parts of the province, but the bidding was by no means spirited, and the sale can hardly be called a very successful one.

Fifteen Cotswold rams were sold. Those put up first, including one or two imported rams, did not fetch good prices, the figures paid for each running from $28 to $34. Prices got better when the one shear lambs were brought out, two being sold at $60 each, one at $51, one at $50, and the others ranging from $50 down to $31. No Cotswold ewes were sold. The bidding on the Southdown rams was not brisk, and only two were sold—a two and a one shear—for $23 each. Some Berkshire spring pigs were sold at from $14 to $16 each, and a sow for $22. Nearly all the sheep were sold to breeders outside of the county.

☞ The Swedes are populating Kansas. One party is purchasing 26,000 acres.

☞ The "Township of Tuckersmith Agricultural Society," South Riding of Huron, has been incorporated.

☞ With all the drawbacks, the present crops in the United States are the largest in many years. Such is the report of the Department of Agriculture, at Washington.

☞ The price paid for flax in St. Mary's is $12 per ton. The *Argus* says that at this price the crop has proved most profitable, and the success attending flax growing will probably induce its cultivation to a still greater extent next year.

☞ The Agricultural Society of North Crosby, in the east division of the south riding of Leeds, having complied with the provisions of the Act, has been incorporated as the "Township of north Crosby Agricultural Society."

☞ The aggregate attendance at the late New York State Fair, at Rochester, is estimated at 68,400. The largest attendance at any State Fair in the State was that held in Rochester, in 1851, the estimate for which is 95,000. The smallest attendance was 27,000 at Saratoga, in 1853.

☞ It is estimated by the Brampton *Bonner* that there are over 100 acres of land under hops in the township of Esquesing. The yield the past season was about 600 lbs. per acre, as against 800 last year; the price last year was from forty to fifty cents per lb., while it is as low as fifteen cents per lb. at the present.

Failure of the Hop Crop in Wisconsin.—The success of hop-growing, and the high prices realized in 1867, gave a great impetus to this branch of agriculture in Wisconsin. It was followed by many even to the extent of neglecting the more important cereals; and the failure of the hop crop this year has entailed heavy loss on thousands both of farmers and merchants.

Prize Wheat.—The prize for fall wheat annually offered by the Canada Company, requires that twenty-five bushels shall be placed at the disposal of the Association for distribution. The following gentlemen, representing, we presume, agricultural societies, have obtained samples:—Phillip Armstrong, West York; Jacob Young, Haldimand; William Beattie, South Leeds; G. J. Miller, Niagara; Josh. G. Fisher, N. Huron; P. M. Shannon, South Bruce; Hugh Love, South Huron; F. W. Stone, Guelph; Hon. Asa A. Burnham, Northumberland; Wm. McCann, North Oxford; Jas. Nimmo, Addington; Chas. Ross, East Elgin. The Canada Company retains two bushels, and, strange as it may seem, about two bushels are carried away every year by visitors at the exhibition.

West Riding of York and Vaughan Show.—On Tuesday and Wednesday, Oct. 20th and 21st, the Union Exhibition of the West Riding of York and Vaughan Agricultural Societies was held in the town of Berwick. Notwithstanding very unfavourable weather, there was a large number of visitors, amounting to as many as 6,000. In the dairy department there was more than usual competition, and the show of implements was specially deserving of notice. Mr. Abell's extensive works are established in the neighbourhood, and this enterprising manufacturer contributed largely to the implement department of the exhibition. Altogether the show was a success.

Algoma Fall Show.—The first exhibition of the Algoma Agricultural Society was held early in October, at Sault Ste. Marie. The Secretary of the Society, in a letter to the *Owen Sound Times*, gives a glowing account of the affair. The grain, roots, and vegetables, he says, were particularly fine, "being much over the provincial average in weight, and every sample of cereals exhibited over the standard weight per bushel measure. The prize oats, four pounds over; barley, five; wheat, six." There was also an especially excellent display of "Algoma's pride," potatoes. The show of stock was of course not large, but creditable. We congratulate the Society on the success of their first agricultural exhibition, and their laudable efforts to bring before the notice of their countrymen, and neighbours in Michigan, the resources of the District of Algoma.

Oxford County Agricultural Exhibitions.—R. W. S. writes that "The exhibitions throughout the County of Oxford have excelled anything of the kind ever seen here before. Upwards of $5,000 have been distributed in prizes (while only $1,400 were received from the Government grant). This is exclusive of expenses attending such distribution. This speaks well for the rising generation of farmers, and shows that a deeper interest is felt in agricultural progress than formerly. It is computed that 6,000 persons attended the North Riding Exhibition, held at Woodstock. 3,500 passed through the Hall, and $181 were taken from non-members. There were nearly 2,000 entries. In grain and dairy produce the show exceeded, by far, the same departments of the Provincial Exhibition. The first six Provincial Exhibitions did not equal the North Riding Show in the number of its entries. The same may be said of the South Riding, which was about the same in the aggregate. Several of our Township shows had 1,400 entries each, and one of them has nearly 500 members. Grain never was better. Roots and fruit are better than was anticipated. Horses and cattle are low in condition. Sheep are as good as usual at the annual exhibitions."

Aldborough Agricultural Show—The Secretary of the Aldborough Agricultural Society has sent us a letter and clipping from the *St. Thomas Home Journal*, giving an account of the Aldborough Show, with the list of prizes. We regret that it is quite impossible to find room for the whole report. Our present issue is already made up, and half the next will be occupied with the Provincial Prize List. The Secretary has our thanks, nevertheless, for his communication. We can only insert the following extract from the printed account referred to:—

"The last agricultural show of the season in this County was held by the Aldborough Society, at Rodney, on Friday, the 16th. It would almost seem as if the Aldboro' people had purposely held back till the last, in order that they might have an opportunity of surpassing all others. But whether this charge of intent can be supported or not, it must at any rate be admitted that Aldboro', with all its drawbacks, its sand farms and chestnut groves, came out No. 1 in the show list this year. No other Society in the two Ridings made so many entries; no other Society sustained so fair an average in the quality of the articles shown.

The entries in each class were as follows:—Horses, 139; Cattle, 92; Sheep, 67; Swine, 31; Poultry, 28; Grain and Seeds, 133; Roots and Vegetables, 69; Horticulture, 38; Dairy, &c., 57; Home Manufactures and Implements 105; Ladies' Work, 84: making a total of 843."

Meeting of the Fruit Growers' Association.

The regular autumn meeting of the Ontario Fruit Growers' Association was held in the Town Hall, St. Catharines, on Tuesday, 13th October, 1868. The meeting was organized at 11.30 a. m.; the President, W. H. Mills, Esq., in the chair. A large number of members were present from different parts of the country, almost all, however, from west of Toronto, and a fine display of fruit was exhibited.

After the reading of the minutes of the last meeting by the Secretary, D. W. Beadle, Esq., the first order of the day was taken up for discussion, viz:—What *varieties* of apples are best for market?

Mr. O. T. Springer, of Wellington Square, being first called upon for his opinion, said that he shipped by boat to Montreal the Early Harvest and Red Astracan, followed by the Primate and Early Strawberry; they arrived in good order, and realized the highest market price. He found the Early Harvest to be liable to spot and crack, and would plant the Red Astracan in preference. He thinks the Primate a good apple for shipping, a good bearer, firmer than the E. Harvest, and a better bearer than the E. Strawberry; can also be shipped a little greener. He values the Fall Pippin higher than any other autumn apple, but this variety requires high cultivation to secure fair, perfect specimens, else the fruit is apt to be gnarled and spotted. The Ribstone Pippin he considers very valuable. The Snow is apt to spot badly unless highly cultivated, but when perfect commands the highest price. His orchard is between Wellington Square Station and the Lake, of a sandy soil, under-drained, with good natural drainage also; it is about twenty years old. He top-dresses in the autumn with barn-yard manure, and gives it ashes occasionally. He finds the Porter very good, but it requires to be picked before it is perfectly ripe. A red-colored apple will always sell more readily than a green or yellow one; besides, it does not show a bruise so soon. Among winter apples he has the R. I. Greening, Roxbury Russet, Baldwin, Northern Spy, and Golden Russet of Western N. Y. He finds the R. I. Greening a very valuable variety for home sale and shipment, hardy, and bearing an abundant crop in alternate years; the Roxbury Russet one of the most valuable, because it keeps so long, even till June. It is a sparce bearer and slow grower. The samples he has obtained have been fine and of sound quality. An objection to it is that the fruit is very subject to the ravages of the codling worm—more than any other winter fruit. The Baldwin has not been altogether satisfactory; it bears well every other year, but is very subject to worms. Out of eight barrels last year, there was one of bad fruit from this cause. It kept till February, but was often rotten at the core when apparently sound outside; when grown on clay it was better. It is a firm, sound fruit, and does not show bruises; hence its value for shipping purposes. The Northern Spy is the most valuable apple he grows; it puts forth its leaves and blossoms seven to ten days later than others, and thus escapes the late frosts; it grows vigorously anywhere, but requires high cultivation to secure the best results. In pruning, all the centre shoots should be cut out, in order that the fruit may colour well, without which it has no good flavour. It should be carefully handled for shipping, as the skin is thin and the flesh delicate. The tree bears every year, but is slow in coming into bearing, not beginning till it is from eight to ten years old. It keeps well when preserved in an even temperature, as late as till June. It hangs well on the tree, and commands a higher price than any other winter apple. The Golden Russet he finds not particularly valuable, perhaps because its situation in his orchard is not favourable; yet it is hardy, and a free bearer. It keeps well, ships well, and bears rough treatment, but withers when long kept.

Mr. C. E. Woolverton, Grimsby, said that the Sweet Bough and Golden Sweet yielded more fruit than the Early Harvest or Red Astracan. The Spitzenberg is the best apple for foreign market that he has, especially in Glasgow, Scotland.

Mr. A. M. Smith had shipped the Early Harvest to Montreal, and they arrived in good order. He considers this variety as good as any, and more profitable than the Red Astracan, because it bears better and ripens more evenly. The Sweet Bough is a good early market apple. The Duchess of Oldenburg is a productive, valuable and handsome apple, and commands a high price. The Fall Pippin and Ribstone Pippin are the best fall apples for market. The Black Detroit sells well; its quality is not equal to the Fall Pippin, nor is the tree a better bearer, but its colour makes it attractive to buyers. The Snow does well with him. He thinks the N. Spy a better apple than the Baldwin, but the latter is more profitable, being more productive. The Spitzenberg produces about two-thirds as much as the Greening. The Roxbury and Golden Russets are very long keepers.

Mr. R. N. Ball, of Niagara, said that for foreign market the Newtown Pippin commands the highest price. The Ribstone Pippin is very valuable, and bears every year. The Baldwin is very profitable. The Golden Russet is not quite as long a keeper as the Roxbury Russet, but is a very valuable market fruit. The Rambo spots very badly with him; his is a clay soil; it does better on mixed clay and sand. (Mr. Morse said that it did well on sand with him). The Greening brings a less price in foreign markets than any other variety—from two to four shillings less than the Spitzenberg. The Roxbury Russet does not take in foreign markets. The Lady apple commands a fancy price. The Newtown Pippin requires a clay soil and high cultivation. He ranks the Green Newtown Pippin first, Ribstone do. second, Baldwin third, for market. The Swaar is too uneven in size. The King of Tomkins Co. is good. Duchess of Oldenburg promises to be a very valuable market apple. The English Golden Russet is hardly as good a bearer as the E. Spitzenberg. The American Golden Russet does not shrivel when kept barreled tight.

Mr. A. Morse, Smithville, said that the Early Harvest is a good apple for local demand, and is a regular bearer; the Sweet Bough and Red Astracan come next; after these the American Summer Pearmain comes in before the fall varieties, and sells readily; it bears every other year. The Fall Jennetting and Duchess of Oldenburg take well and sell well. He thinks highly of the Dutch Mignonne, as it is a prolific bearer, of showy appearance, and sells well; the tree is very hardy; the fruit keeps till the first of January. The Golden Russet has never failed to yield a good crop. The Spitzenberg, Baldwin, N. Spy, Greening, and Twenty-ounce Pippin, all do well. The Talman Sweet bears indifferently with him; it may be owing to its position in a dark river bottom soil. None of the trees on this bottom do as well as those higher up. The Snow does not succeed well with him. The King of Tomkins Co., Cayuga Red Streak, Jersey Sweet, Ribstone Pippin, Gravenstein and Alexander, thrive and bear well. He showed a new large green-coloured cooking apple, ripe in October and November, a good bearer, with crops every year.

The Hon. D. Reesor, Markham, said that he finds the best early apple is the E. Harvest. The Red Astracan is not quite so good in quality. The Fall Pippin and Blenheim Orange are the best autumn apples. The Twenty-ounce apple and Cayuga Red Streak are good. The Snow is sometimes scabby, yet the same tree, with the same cultivation, may next year yield fine fruit. The Esopus Spitzenberg stands highest among his winter fruit. The young trees in the nursery are sometimes killed by the winter, while in the same neighbourhood this variety grafted on the top of standard seedlings has endured the winter well and borne good crops of fruit. The Baldwin is a fair bearer, but the fruit is not so perfect or as fine in flavour as the E. Spitzenberg; it has not, however, had as long a trial with him. They have not had very severe winters since the Baldwin has been fruiting in their neighbourhood. The R. I. Greening is an excellent bearer and a favourite fruit; taking its qualities together, productiveness, flavour and keeping powers, it is much esteemed. The Am. Golden Russet is a good bearer, keeps well, and is of good quality. The Ribstone Pippin on good soil, and when well cared for, bears well; its flavour is usually good, but he has seen something of watercore and dry rot in it. Has seen the dry rot also in the Baldwin, even to a greater extent than in the Ribstone Pippin. The Snow [illegible], on [illegible] clay soil, sixteen miles north of Lake Ontario, [illegible] to fine perfection; when sent to Glasgow five years ago it brought from $8 to $10 per barrel.

Rev. R. Burnet, Hamilton, remarked that the Ribstone Pippin was late in leaf and flower, and hence frequently escaped the later frosts of spring. The apple was generally agreed upon by those present to be the best variety of all when well cultivated, the N. Spy ranked next.

Mr. A. Leslie, of London, recommended the Red Astracan and Duchess of Oldenberg; the Early Harvest was apt to get spotted and wormy. The Sweet Bough succeeds well. He values the N. Spy among the first of the winter apples; the Baldwin he considers tender; the Spitzenberg variable; the R. I. Greening and Golden Russet good; the Snow succeeds well and is a good market variety. The Talman Sweet bears heavy crops on all soils, but is not appreciated; Esopus Spitzenberg not a general bearer. He exhibited a seedling apple that keeps well until January 1st, and even till March, but then has lost its flavour; it is good both for cooking and dessert.

Mr. O. T. Springer exhibited a new seedling; it was a medium-sized, showy apple, a good dessert fruit, keeping until 1st of March, from a vigorous growing tree, very hardy, and a good annual bearer; the flavour of the fruit is sub-acid, sprightly, juicy.

Picking and Packing for Market was the next subject for discussion. Mr. R. N. Ball, Niagara, being requested to describe his method, said that apples should be picked as soon as mature, and then kept in a heap till they sweat, which he considered far better than putting in barrels at once, as it prevented shrivelling. For appearance they should be placed stem down. The barrel should be shaken gently during filling, filled up to the top, and then pressed down about an inch and a half to admit the head, using a pressure of five or six hundred lbs. Only first-class apples need be sent to Europe; any others will prove unremunerative. Two grades might be sold in Canada, but he considered second-class fruit only fit for cider. By a first-class apple he meant one that is free from worms, blotches, and bruises, carefully picked off the tree by hand, and of the average size and form of its kind. He preferred using baskets to sacks for picking, reaching tall trees by means of ladders. When filled and headed the barrels should be laid on their sides.

Mr. Latshaw, of Paris, said that each variety of apple has its own season of maturity, and should be picked in accordance with it. He prefers to dry weather to pick, sort, pack, press and head up in barrels at the tree at once, and all on the same day, leaving the barrels out of doors as long as the weather is fine; they will then keep well, and can be shipped to Egypt or anywhere else. This is his practice and experience. He has put up in this way from one hundred and fifty to two hundred bbls., and shipped them to New York, where they have come out perfect. The fruit should, of course, be picked dry, and not opened till it is wanted; and only varieties that keep should be put up.

Mr. Stewart, of Goderich, said some Baldwins were put up in a rough way in barrels, sent to Glasgow, and then forwarded inland some one hundred and fifty miles by rail, and they arrived safe and sound. He said they should be well pressed from a round heap above the barrel to flat.

Mr. Ball said that first-class tight barrels, made with split staves, should be used, and then there would be no shrinkage.

Rev. C. J. S. Bethune, of Credit, on request, gave a very clear and interesting account of the insect which was at work upon the trunk of a young apple tree, brought to the meeting by Mr. Smith, of Grimsby. It was the Buprestis borer, *Chrysobothris femorata*.

The meeting next proceeded to the consideration of Plums,—The best varieties, and the best methods of preventing the black-knot, curculio, and other insects.

Mr. Lewis, of Niagara Falls, stated that he had been for some time trying to grow plums, but they always dropped off when half grown. He had tried throwing lime into the tree, but it did no good.

Mr. Martin, of Cayuga, found that they did better on clay than sand, and better in gardens than on lawns; the green varieties suffered less from both black-knot and curculio than the purple. He has plenty of fruit, and has taken but little pains with his trees.

Mr. R. N. Ball stated that a friend in Hamilton, who had manured his plum trees with tobacco stems and refuse from a factory, had not been troubled with the curculio since.

Mr. Read, of Port Dalhousie, cuts a semi-circular notch in the end of a long stick, lines it with an old India-rubber shoe, and with it jars his trees, placing under them a sheet, split half-way up the middle to admit the trunk of the tree, and with slats nailed to

the ends to keep it from moving about. He jars the trees regularly every morning from the first formation of the plum until the stone hardens, and destroys every curculio and plum that falls upon the sheet. By the aid of two of his children he performed the work very quickly and with little trouble. He always has a good crop now, and saves also his nectarines and apricots in the same way.

Mr. Ball finds that a few good sharp-set hogs in the plum orchard keep the curculio under.

Rev. Mr. Bethune thinks it now well established that the black-knot is produced by a fungus, and not by an insect, and that it can be kept under by prompt amputation. The insects found in it merely make use of it as a convenient abode, and are not the authors of the trouble. He considers that the only effectual remedy for the curculio is that described by Mr. Read, viz., jarring them off by sharp blows into a sheet spread below, and destroying those that fall by fire or boiling-water; also gathering up the fallen fruit as fast as it falls, and destroying it with the living larva inside. He recommends, where practicable, keeping hogs in the orchard, who will destroy not only the curculio but also the codling worm.

Rev. R. Burnet has found that the curculio very seldom travels much, and that one may be quite sure of saving the fruit in his own garden by this jarring and killing process.

Hon. D. Reesor wished to caution the public against turning too large and too hungry hogs into orchards, as he has known an entire young orchard badly injured by the hogs eating the bark of the trees.

Mr. John Freed said that he had put a quantity of tobacco stems under his plum trees, six inches deep, also some in the branches, but the curculio did not seem to be inconvenienced by it in the least; one of his neighbors keeps his hogs in his orchard, and finds that they do good service.

Mr. J. Arnold, of Paris, whitewashed the ground under several of his trees with a thick coat until it formed a crust; the curculios did not trouble those trees, but affected all the rest.

Mr. W. H. Mills, of Hamilton, said that the brightness of the white surface kept the curculio from the trees so treated and drove them to the others, and that if Mr. Arnold had whitewashed beneath all his trees he would have found that the curculio would have attacked all alike. He himself found nothing equal to the jarring process.

Hon. D. Reesor enquired whether salt under the trees would kill the curculio. Mr. Beadle replied that the experiment had been tried, and that the grub was seen to creep through several inches of salt uninjured.

With regard to varieties, Mr. W. H. Mills thinks highly of the Columbia as a cooking plum; it ripens unevenly, and is, therefore, a long time in use; the tree is hardy. Reine Claude de Bevay is too late with him; Jefferson is a fine plum; Victoria is large, better than Pond's seedling, Guthrie's Apricot plum was sent by Mr. Saunders, of London; a very fine flavored plum.

After an adjournment of an hour the meeting reassembled at 7 p. m., and proceeded to the discussion of the best variety of GRAPES.

Mr. A. M. Smith thinks the Adirondac the best earliest grape; his vine has endured the winter so far well; it is a good bearer, and is earlier than the Delaware. Mr. Martin agrees with him.

Rev. R. Burnet, Mr. Holton, and Mr. Freed have not the Adirondac; with them the Hartford Prolific is the best and earliest grape.

Dr. Smith, of Komoka; Mr. Stewart, of Goderich; Mr. J. B. Lewis and Mr. A. Leslie, considered the Delaware the best.

Mr. Farrell, of Cayuga, finds the Delaware and Rogers' No. 5 ripen about the same time; he prefers the latter.

Mr. C. Arnold finds Rogers' No. 3 better and earlier than the Hartford Prolific, and with him the best earliest grape.

Mr. Read considers the Delaware the best earliest, and the Laura Beverly far superior to the H. Prolific, of a better flavor than the Concord, and equally hardy.

Mr. Jas. Taylor, of St. Catharines, thinks highly of Rogers' Hybrids, yet he finds some variableness in them. No. 33 is not as fine this year as last. The Laura Beverly is so like the Crovelling that it is not easy to say that there is any difference.

Mr. Morse, of Smithville, has the Concord, H. Prolific and Delaware; of these the last is the earliest—it was nearly ripe on the 30th August.

Hon. D. Reesor knows only the H. Prolific and Delaware of the early kinds; he prefers the latter. In his neighborhood (Markham) these grapes are covered in winter.

Mr. Bauer, of Hamilton, places the Delaware first; he has tried it seven years in all exposures, both North and South, and has had them ripen on the first of September.

Mr. W. H. Mills has a few varieties:—Delaware, Rogers' Nos. 3 and 4, and some others. He considers the Delaware the very best earliest variety; Rogers' No. 4 ripened the same time as it, and a week earlier than No. 3.

The next topic was the *best varieties for market.*

Dr. Cross was at Hammondsport, N. Y., where a large business is done in marketing grapes; only Catawba and Isabella are grown there, of which the latter is found the most profitable. He himself finds the Isabella on his own grounds more profitable than the Concord.

Mr. Arnold thinks we know but little on this subject; he prefers Rogers' 4 and 15.

Mr. Read considers the Concord and Ontario to be the most prolific; the latter sells most readily on account of its large size. Mr. Taylor confirmed this opinion respecting the Ontario.

Mr. Martin packed the Sweetwater tightly with severe pressure in a box, and sent it to New Brunswick in good order.

Mr. Lewis sold his Isabellas on the vine at four cents per pound; thinks he could have obtained ten cents per lb. for Delawares.

Mr. Stripp finds the fruit dealers do not think much of the Isabella when grown in this Province, as it does not ripen well enough. The Concord ripens well and sells well.

Mr. Freed found the H. Prolific sell better than the Concord. It was generally considered that a large, showy grape sold better than a smaller and finer variety.

The *soils* best adapted for the several varieties were next considered.

Mr. Smith has a sandy loam, on which the Concord does best.

Dr. Cross has a clay loam, well under-drained, on which the Isabella does best, the H. Prolific next; the Delaware fails utterly. They were heavily manured when first planted.

Mr. Farrell said that his best vines grew on a light soil, but the Delawares did better on a soil somewhat clayey.

Mr. Taylor has a clay loam, on which all do well. The Diana succeeds, and he values it very highly. He thinks we are in danger of manuring too much. Allen's Hybrid is his best white grape, but it is subject to mildew.

Mr. Stewart has a light soil, on which the Delaware and Concord do best.

Mr. Arnold's soil is a mixture of clay and sand with a limestone bottom. The Delaware and Diana do not succeed, but some of Rogers' and his own Hybrids do very well.

Mr. Read's soil is a sandy loam, on which all seem to do well; he has a piece of clayey loam, on which he finds his best specimens. He prefers a rather stiff loam.

Mr. Martin has a strong loam; he thinks that those kinds which make a vigorous growth and have a large leaf do best on clay.

Hon. D. Reesor has a stiff clay loam, on which he has the Delaware of a fine quality, though the quantity has not been large nor the growth rapid. The Concord grows pretty well, but does not bear as much as the Isabella.

Mr. Bauer has a black clay loam, on which the Diana and Delaware do well and are free from mildew; they seem to ripen as early as in Ohio.

Mr. Lewis has a black loam, bordering on clay; all varieties do well.

Mr. Stripp found those Delawares on gravelly limestone soil sweeter than those on deep sand. The Concord when on limestone gravel produced the largest crop.

Pruning and Training of Grapes was next in order for discussion.

Dr. Cross thought that every vine required pruning adapted to its growth, soil, and habit, and that the heaviest pruning should be done when the leaves are off, doing but very little in the summer.

Mr. Farrell succeeded best by a rigid system of pruning.

Mr. Taylor tries not to leave too much wood, but to prune enough to give good well-ripened wood.

Mr. Read trains to a single stake, and prunes according to the age and variety of the vines, leaving buds for fruit accordingly. He does not pinch or prune in summer, but in the fall.

Mr. Martin does not prune in summer.

Mr. Bauer does no summer pruning beyond keeping the stock free from shoots or suckers up to eighteen inches above the ground.

Mr. Lewis prunes just after the vine comes out in leaf, as in winter pruning the cane dies back two to four inches from the place where it is cut; he does no pruning in summer.

Mr. Stripp thought the Diana as vigorous as the Concord, and requiring to be pruned longer than the Delaware.

The meeting then proceeded to taste and discuss the seedling grapes exhibited by Mr. C. Arnold and Mr. Read. Of Mr. Arnold's varieties, No. 8 was almost unanimously considered the best table grape; Nos. 5 and 16 being next in estimation. No. 16 was deemed a fine wine grape by Mr. Bauer; while the producer esteemed No. 2 above the rest. The only draw back to them was their want of size, which will probably be obviated when they are cultivated in a more favorable soil and climate than that of Mr. Arnold's garden. On motion the following resolution was unanimously adopted:—

"This meeting begs to tender to Mr. Arnold a vote of thanks for exhibiting his new Hybrid Grapes, and earnestly recommends them for trial in all parts of the Province."

Mr. Jas. Taylor stated that he had fruited No. 1, and found it much better in his grounds at St. Catharines than the sample shown by Mr. Arnold, grown at Paris.

Respecting Mr. Read's new grapes, the verdict of the meeting was strongly in favor of his Silver Cluster, which was considered to be of a fine delicate flavor of high value. His Hattie and Dominion were also much commended.

Before the close of the meeting the Committe on the fruits exhibited reported as follows:—

"Your Committee appointed to inspect and report upon the fruits before the meeting, beg to present the following:—

Rev. R. Burnet—1 variety of pears, 5 grapes, 9 apples.
Hon. D. Reesor—2 pears, 12 apples.
D. W. Beadle—12 grapes.
W. H. Mills—3 pears, 5 grapes, 3 plums.
W. Saunders—2 pears, 4 grapes, 5 plums.
A. Leslie—1 seedling apple.
W. Holton—22 pears, 8 apples, 1 quince, 3 crabs.
J. Freed—3 pears, 6 apples, 1 quince, 1 crab.
Mr. Latshaw—8 apples.
A. Morse—1 seedling apple.
W. H. Read—14 grapes.
C. Arnold—4 pears, 5 seedling grapes, 6 apples, 2 raspberries.
Wolverton and Smith—6 pears, 5 apples, 2 peaches, 2 quinces, 1 crab.
O. T. Springer—8 apples.

The foreign grapes exhibited by Rev. R. Burnet, and grown by him in the open air, were remarkably fine, particularly the Sweetwater, and a variety called the Hungarian Princess.

In apples the Committee remarked fine specimens of King of Tompkins Co., N. Spy, Boston Russet, Fameuse, Baldwin and Waggoner.

In pears, large well-grown specimens of Duchesse, Vicar of Winkfield, Howell, Swan's Orange and Washington were observed.

The show of plums, though not large, contained fine specimens of Reine Claude de Bevay, Guthrie's Apricot, Denniston's Superb, Bingham and Columbia.

The display of grapes was large and attractive. Amongst the newer sorts fine bunches of Isabella, Ionn, Rogers' number 19 and Adirondac were noticed, and the new Canadian seedlings of Messrs. Arnold, Read, and Rev. Mr. Dixon attracted particular attention.

Your Committe noticed with great pleasure the hybrid raspberries presented by Mr. Arnold, and from the apparent hardy character of the cane with its free-bearing habit, being now loaded with ripe fruit, they think it must prove valuable.

Several varieties of crabs were on the table, and the attention of your committee was drawn to a promising seedling of our native *Pyrus coronaria*, or wild crab, showing what improvement may be hoped for by a little effort in that direction.

Respectfully submitted,

(Signed) CHARLES ARNOLD,
JOHN FREED,
W. HOLTON."

MEETING OF DIRECTORS OF THE FRUIT-GROWERS' ASSOCIATION.—On the day after the general meeting of the Fruit-Growers' Association, the Directors met at St. Catharines, for the transaction of business. The subject of offering prizes for the best seedling apples of Canadian origin, was discussed, and although action was deferred until a future meeting, it was the opinion of all that it was desirable to secure additions to the present list of varieties of such as were *very hardy* as well as productive, and of fine quality. The subject of an experimental garden, in which new varieties of fruits should be thoroughly tested, was also considered, but no action taken. The next meeting of the Association was ordered to be held at Hamilton, on a day to be fixed by the President.

Report of the Committee on Prize Essays.

TO THE CHAIRMAN OF THE DIRECTORS OF THE FRUIT GROWERS' ASSOCIATION.

SIR,—The Committee appointed by the Fruit Growers' Association of Ontario to judge of the relative merits of the essays on the apple and its cultivation as applicable to the Province, beg leave respectfully to report:

That four Essays were submitted to their consideration, bearing the following mottoes, viz.: "The price of good fruit is eternal vigilance." "*Vive et discе.*" "Here's to thee, Old Appleton." "Fine fruit is the flower of commodities." That all the Essays are of superior excellence, and that your Committee had some difficulty in arriving at a satisfactory conclusion as to which was the best.

That the Committee are unanimous in the opinion that the paper with the motto, "The price of good fruit is eternal vigilance," is fairly entitled to be considered the best treatise on the apple, and its cultivation as applied to the Province, and to it, therefore, they award the prize. That they have come to this decision from the admirable arrangement of the Essay, the correct statements on every particular item passed in review, and for the judicious and exhaustive list of the varieties of the apple, as at present known, adapted to the Province.

They further report in reference to the prize Essay, that they find that about two-thirds of the whole are taken up with the important subject of insect pests—a subject yearly pressing itself on the attention of fruit growers; but they cannot but express the thought that in an Essay of eight octavo pages, or thereabouts, that the amount of matter on this point, valuable as it is, is out of due proportion. And further, that the matter of protection to the orchard is overlooked.

Your committee also report in reference to the Essay with the motto, "*Vive et discе,*" that it possesses many excellencies, and that great good might result from its publication. They much regret that the terms of competition did not allow of a second prize, as they are firmly persuaded that with a few emendations valuable results would follow from its also being given an extensive circulation.

That your Committee return the letters with accompanying mottoes unopened, to be dealt with as the Chairman and Secretary of the Board may deem fit.

All which is respectfully submitted by

WARREN HOLTON,
ROBERT BURNET, } *Committee.*

The Apple and its Cultivation, as Applicable to the Province of Ontario.

PRIZE ESSAY.—BY D. W. BEADLE, ESQ., ST. CATHARINES.

THE SOIL. It is essentially requisite to the health and longevity of the tree and the perfect developement of the fruit, that the soil on which it is planted be perfectly drained. If such a condition does not exist naturally, it must be secured by artificial means; to plant the apple where the roots must be soaked with excess of water during any large part of the year, can only be productive of disappointment and loss. This having been secured, all other questions concerning the soil are of little moment. Any soil that will produce a good crop of corn or potatoes will be found well suited to the apple. No doubt a strong calcareous loam is the perfection of soils for the apple, but with proper care they can be made to thrive well in sandy soils or in a stiff clay. A strong clay is preferable to a light sand. All soils should be thoroughly tilled, and made as mellow as for a crop of grain before planting; and after planting should be kept mellow and loose by cultivation while the trees are growing. Hoed crops are the best for this purpose to raise in an orchard; no doubt the very best way is to keep the ground thoroughly cultivated without any crop, but that is not to be expected of the most of our farmers, who hardly feel able to till the soil so many years without any returns.

TRANSPLANTING. The season for performing this operation is in the autumn after the fall of the leaf, or in the spring before the buds break. In this climate experience seems to indicate the spring as the best season. Care should be taken to preserve the roots from bruises and mutilations in the process, and to settle the earth well about them when filling up the hole. In very stiff soils it is better merely to scrape away some of the surface soil, spread out the roots in their natural positions, and then cover them well with surface soil. The trees should be staked and tied firmly, so that they will not be swayed about by the winds, and in tying them let it be with strips of leather or woollen, and in such a way as not to cut into the bark of the tree. Before the heat of summer comes on, the trees should be mulched, that is, the surface of the ground under the trees, a little farther than the roots extend, should be covered with coarse manure or litter from the barnyard, or with chip manure from the old wood-pile, or spent tan-bark, in short, with anything that will keep out the heat of the sun and keep the soil cool and moist. When transplanted trees require watering, the water should be given abundantly, so that it shall descend to the roots; a superficial watering that only moistens an inch or two of the surface is usually worse than none.

CULTIVATION OF ORCHARD. Until the orchard comes into bearing, it ought to be thoroughly cultivated and the soil kept mellow and loose. There can be nothing worse for a young orchard than to seed it down and let it lie in grass. The trees should be pruned so as to form an open head, and keep the branches from crossing each other or interlacing. A little pruning each year will accomplish all this, and is much better for the trees than a severe pruning once in several years. The best season for pruning in this climate is the month of April. This gives the wound an opportunity to heal over during the growing season. When it is necessary to remove large branches, the cut should be covered with grafting wax or clay, so as to prevent the exposure of so large a surface to the weather. It is a very bad practice to prune late in the fall; the action of our severe winters upon the fresh wounds is injurious to the tree. It pays well to manure the orchard and keep the ground in as good condition as a good farmer will keep his corn fields. A dressing of leached ashes or of lime put on once in three or four years will be found very beneficial. Attention should also be given to all insects found destroying the foliage or injuring the bark or boring into the wood of the tree; the same kind of attention that would be given to a dog found killing your sheep.

INSECTS. The several kinds usually found seriously injuring the apple trees in this Province will be briefly described, and the best known methods of destroying them stated.

THE ROSENDO, (*Macrodactylus Subspinosus*). This little beetle has not as yet been very generally distributed, but where it has appeared in large numbers it has been very destructive. It is about one-third of an inch in length, slender body, entirely covered with thick, short, ashen yellow down. Its slender legs are pale red, and the joints of the feet, which are very long, are tipped with black. They come out of the ground during the second week in June, or when the roses are in bloom, and stay about forty days. At the expiration of this time the males fall on the ground and die, while the females enter the soil, where each lays about thirty eggs, at a depth of from one to four inches below the surface; they then return to the surface, and in a few days perish. In about twenty days after the eggs are laid, they are hatched, and the little grub feeds on such tender roots as it can find, completes its growth in the autumn, at which time it attains to about three-quarters of an inch in length and one-eighth in diameter, and is of a yellowish white color, with a tinge of blue towards the posterior extremity. In October, the grubs descend so as to be protected from the frost, pass the winter in a torpid state, and in the spring return near the surface, where each forms a little oval cell; within this cell the grub, during the month of May, casts off its skin and becomes a pupa, out of which, in the month of June, the perfect beetle comes forth and digs its way out to the surface of the ground. These beetles are, apparently, omnivorous, eating the leaves of roses, rosebuds, pear, plum, cherry, grape-vine and apple, and where they appear in large numbers they are exceedingly destructive. They also seem to defy all the ordinary applications which have been found destructive to insect life, so that the only well attested and reliable plan seems to be that of catching and killing them. Nor is this very difficult, for their habits are so sluggish and they congregate in such masses, that an active boy can catch and destroy a great many in a day. Whenever they make their appearance no time should be lost, for although they may at first only attack the rose-bushes or even the weeds of the garden, when their numbers have increased, as they will, and that at the rate of five and twenty in a season for every pair, nothing that has leaves will be safe from their ravages. If they have seized upon the apple-trees, they must be shaken down, and gathered and burned or put into scalding water. It would be well worth the trouble to sprinkle a bush upon which they are feeding with white hellebore, diffused in water, say at the rate of two tablespoons full of powder to a common pailful of water, well stirred, and [illegible] with a co[illegible] pot, and see whether they can be killed by [illegible] that poison.

THE BORER, (*Saperda bivittata.*) This b[illegible] become very destructive to young orchards, and [illegible] its mischievous work so silently and [illegible] observation that the labour of years has been entirely ruined before suspicion was [illegible] any danger threatened. The perfect [illegible] brown on the upper side, marked with two [illegible] stripes running lengthwise of the body; the under side, the face and the antennæ, and the legs, are white. It is usually about three-quarters of an inch in length. It comes out of the trunks of the trees in June, moving about during the night, and remaining concealed by day among the leaves. During June and July the females deposit their eggs upon the bark of the tree, near the root, at that part usually known as the collar. From the eggs are hatched little fleshy, whitish grubs, without feet, which eat through the bark, and on reaching the sap-wood, excavate a round, smooth cavity, about the size of a dollar, immediately under the bark. It casts out of a hole, which it makes at the bottom of this cavity, its excrements, which appear like very fine sawdust, so that at this stage the presence of this enemy can be readily ascertained by searching for this dust on the ground at the collar of the tree. When it has become about half grown it ceases to cast the dust out of this cavity, and proceeds to fill it up, at the same time boring a passage or gallery upward into the heart of the tree. This gallery is continued upwards of varying length, sometimes not more than two inches, and sometimes twelve inches, and is gradually brought outwards again to the bark of the tree, but not through it. When the grub has completed this gallery, it turns round and returns to that part which is the nearest to the heart of the tree. This part it now enlarges by tearing off the fibre from the walls, and with this fibre carefully and securely closes the entrance, so that if some insect enemy should find its way through the hole in the bark at the collar, into the chamber where it passed the first part of its life, that enemy could not enter the gallery to its present abode. Meanwhile it crowds its sawdust-like castings into the upper extremity of the gallery against the bark, thus at the same time diminishing the danger of attack from that quarter, and keeping its new chamber tidy. Having thus perfected its arrangements, it again turns round so as to have its head upwards, passes the winter in a torpid state, and in the spring, casts off its skin and becomes a pupa, from which in June the perfect insect hatches, climbs to the upper end of the gallery, tears away the fine sawdust, gnaws a hole through the bark, and creeps forth.

It will readily be seen that when several of these worms are at work in any tree, their chambers approach so near each other as to girdle the tree. Unfortunately they are distributed all over our country, and no apple orchard can be considered safe from their ravages; indeed many have been seriously injured, and others wholly destroyed, before the cause of the mischief was suspected.

There are two ways of combating this enemy; the one is a way of prevention, the other one of cure. An application of soft soap (cold-made ropy soap is preferable to the hot-made jelly-like soft soap) to the body of the trees, especially about the collar, if made the first of June, and again the first of July, will preserve the trees from the attacks of this insect. It is well to place a handful in the forks of the branches where they separate from the trunk, to be dissolved by the rain and run down the tree. Young and thrifty trees are the favorite resort of this beetle, and they should be especially looked after and rubbed with soft soap.

The cure, when the grub has once effected a lodgement, is simply to catch and kill him. By examining the bark at the collar in the end of August, scraping the outer surface so as to detect any black spots in the bark, the newly-hatched grubs may be found before they have cut their way into the wood, and be killed. In addition to this search, let this part of the tree be washed with strong lye; this will penetrate into the holes and kill any little grubs that have escaped detection. At the same time search should be carefully made for the fine saw-dust castings, which indicate a larger worm within, and if these are seen the excavation in the sap-wood under the bark should be found, and the occupant destroyed by cutting into his hiding place with a stout-bladed knife or chisel. If he has made a gallery into the heart of the tree, the upper opening may be found usually from three to six inches directly above the chamber in the sap-wood, by sticking a pin into the bark until, by the ready sinking of the pin, the exact spot is known; then, with the point of the knife cut away the bark and pour some of the lye into this hole until it soaks through into the chamber below, thus giving evidence that it has passed through the gallery and met the foe. The search for these saw-

dust cuttings should be renewed at intervals through the fall, winter and early spring, so that none of the borers shall escape.

The Bark-louse (*Aspidiotus conchiformis*). In every part of the Province this destructive pest may be found. Its appearance is that of a minute scale, in form like a muscle or an oyster-shell (hence the name *conchiformis*, shell-shaped), adhering to the bark of the tree. It is about an eighth of an inch in length, colour brown, or nearly that of the bark; and, in the winter and spring, will be found to cover from a dozen to a hundred eggs. Towards the end of May these eggs are hatched, and the young larvæ scatter themselves over the tree. These, after feeding on the juices of the tree, are changed into pupæ, and then into the perfect insect, the males only having wings, and, after pairing with the females, perish, while the females remain on the tree. Their bodies dry up and form the scale covering the eggs that susequently are hatched into another generation. The best remedy for these insects seems to be a sort of paint, made by boiling leaf tobacco in strong lye until it becomes an impalpable pulp, and then mixing with it cold-made soft soap (which is ropy, not the jelly-like soap) until it is about as thick as paint is usually applied, and, with a paint brush apply it to all parts of the tree where these bark-lice are found, before the buds swell in the spring. If this be carefully and thoroughly done, the bark-lice will be surely killed, and the tree will make a thrifty growth.

The Tent Caterpillar (*Clisiocampa Americana*). This enemy of our orchards is also distributed throughout the Province. As the buds of the apple trees burst and the young leaves put forth, the young caterpillars are hatched on some warm damp day, and creeping out of the eggs feed upon the soft glutinous substance with which they are covered. When this is consumed, they move down the limb, and selecting some convenient fork, spin a web or tent. This tent is their place of abode, from which they go in search of food, and to which they return when they are satisfied, all going out and returning together in regular procession. When full grown, they are about two inches in length, color deep black with a white stripe extending along the back, and on each side of this stripe are numerous, irregular yellow lines, and a row of pale blue oval spots. About this time they leave their tents, and are scattered about seeking some secure place in which to spin their cocoons. These are oval, pale yellow, loosely woven, and the meshes filled with a fine powder resembling sulphur. In this cocoon the caterpillar changes to the pupa state, and from the pupa comes forth the moth, which works its way out at one end of the cocoon. The moth is of a dull reddish buff colour, with two parallel, nearly white stripes, or bands, running obliquely across the fore wings. Early in July they are the most abundant, and in a few days after they come out of the cocoons, the females lay their eggs upon the twigs of the trees in a broad belt, usually encircling the twig, and cover them carefully with a thick coating of glutinous matter, which serves to protect the eggs until the next spring, and then become the first food of the newly-hatched caterpillars.

The best method of destroying these insects is to search the orchards carefully early in the spring, before the buds are swollen, and take off all the belts of eggs from the twigs and burn them. These belts will be found from one inch to twelve from the end of the shoot, and as there are about three hundred eggs in a belt, the gathering of these is a very rapid way of destroying the insects. Yet some will probably escape observation, and it will be necessary to pass through the orchard just as the young leaves make their appearance, and search for the webs or tents in the forks of the branches, and by means of a light ladder ascend so as to be able to grasp the nest in the hand, which may be covered with a good thick buckskin mitten, and crush the worms. It will be necessary to go through the orchard several times, until every tent is destroyed and there are not sufficient stragglers left to form another.

There is another caterpillar much resembling the foregoing, which sometimes gets into the apple orchards, and which was very abundant during the past summer (June, 1868) in the orchards between London and St. Thomas. This caterpillar is *Clisiocampa Sylvatica*—the Forest Tent Caterpillar, and may readily be distinguished from its congener by the row of white spots along the middle of the back. Its nests or webs are not placed in the forks of the branches, but along the side of the trunk or of some of the larger limbs, and is of so slight a texture as to be seldom seen. When nearly grown, they congregate together upon the trunk or some large limb when at rest, and may be then killed in a body. Fortunately they very seldom appear in such legions innumerable as swept over the orchards near St. Thomas last June; but when they do come, the only possible method of saving the orchards is to make a business of killing the caterpillars.

The Codlin Moth (*Carpocapsa pomonella*). This little insect does not feed upon or in any way injure the trees or their foliage, but when numerous make sad havock with the fruit, causing it to drop prematurely, and disfiguring it with their burrows and rendering it useless. The perfect insect or moth is quite small, yet one of the most beautiful of a beautiful tribe. The expanded wings will scarce extend over three-quarters of an inch; the fore wings are crossed with numerous grey and brown lines, most beautifully scalloped, giving at a little distance the appearance of a watered silk, and near the hind angle of each of the fore wings is a dark brown oval spot, edged with a bright copper color. The hind wings are a light yellowish brown, as lustrous as satin. During the month of July these moths deposit their eggs in the cavity at the blossom end of the fruit; in a few days these are hatched, and the little caterpillar eats its way into the apple to the core, where it feeds upon the fruit until it has attained its full size, at which time it is of a light pink or flesh color. About this time the fruit usually falls to the ground; the caterpillar soon after makes its way out of the fruit, seeks a hiding place, very frequently under the rough bark of the tree, and here spins a thin silken cocoon, like very fine tissue paper, in which it changes into a chrysalis. Some of these are hatched in a few days, and the moths which come out of them lay their eggs in the blossom end of the fruit that had escaped before, and from these eggs is hatched a second brood of caterpillars, many of which find their way into our fruit cellars in the apples. Yet the greater part probably remain in the cocoon all winter, and do not come forth as moths till the following spring.

The remedy for these fruit eaters is to destroy them. This can be done by gathering the fallen fruit every day and using it in such a way as to kill the caterpillars within, or by allowing swine to run in the orchard and devour the fallen fruit. Also by placing pieces of old carpets or other cloths in the forks of the trees, or twisting a straw band around the trunks of the trees, for the caterpillars will seek these as convenient hiding places and here form their cocoons, where they can be easily found and destroyed. Also by building numerous little fires in the orchard about the end of June and during July, for these and many other moths, attracted by the light, will fly into the flame and be burned.

Varieties.—A large part of the Province is well adapted to the culture of the apple, and with the exception of the very cold and exposed sections, nearly every variety can be grown. Yet the really valuable varieties are not many, and those that are profitable to the orchadist are still fewer. Of course there will be personal preferences, and as tastes vary very much the nurseryman's list is necessarily large, so as to meet the various and often conflicting wishes of his customers; but he is by no means a wise man who plants a tree or two of every variety he finds in the catalogue, and he will wish when they come to bear that his collection was more select. It will usually be found that an orchard for family use, comprising the following varieties, will give good returns in fruit and, furnish a supply throughout the season, namely:—For summer, the Early Harvest and Red Astracan as sour apples, and the Sweet Bough; for early autumn, the Duchess of Oldenburgh; Gravenstein, Primate, and Jersey Sweet; for late autumn and early winter, the Ribston Pippin, Hubbardston Nonsuch, Fall Pippin, and Snow Apple; for mid-winter to March, the R. I. Greening, Northern Spy, Esopus, Spitzenberg, Pomme Grise, and Talman Sweet; for spring, the Golden Russet and Roxbury Russet. With these varieties there will be plenty of good apples until the strawberries ripen.

For market, the most profitable varieties are Red Astracan, Duchess of Oldenburg, Gravenstein, and Hubbardston Nonsuch, ripening in the order in which they are named, for a near or home market; and for shipping, the R. I. Greening, Baldwin, Golden Russet and Roxbury Russet, will yield the largest pecuniary returns.

In the colder parts of the Province, those parts that are removed from the influences of our large lakes and rivers, it is necessary to plant the hardier varieties. The following will probably succeed well in any part of the Province, and will give a succession of really good fruit, namely, the Red Astracan, Duchess of Oldenburgh, Saint Lawrence, Snow Apple, Borassa, Pomme Grise and Golden Russet. If there be any spot so chill and inhospitable that these varieties will not thrive, recourse must be had to the still more hardy crabs, of which the Yellow Siberian, Golden Beauty, Montreal Beauty, Transcendant and Ilyslop Crabs, are the best.

Harvesting.—A little care and expense bestowed upon the gathering and putting up of apples intended for market or for winter use will be found to be a very profitable investment. The fruit should be carefully gathered by hand, so that it shall not be bruised, and then should be carefully sorted. Usually it will be found most profitable to make three grades, the first composed of fair, full sized, perfect fruit; the second of the sound but smaller sized apples; the third of inferior sized, knotty, scabby, wormy or imperfect specimens. The first grade will bring the very highest price, the second may either be kept for home consumption or sold at as much or more per barrel than could have been obtained for the lot unsorted, and the third may pay to make into vinegar. A reputation once obtained for putting up apples according to quality will cause that brand to be sought after, and secure a ready sale at the best prices. A little practice will enable one to barrel the fruit securely, first paving the bottom, and gently shaking down as the barrel is being filled, and pressing in the head with just enough of pressure to keep the apples from shaking in the barrel. After securing the hoops, the barrel should be marked on what was the bottom, so as to be opened from that end, then laid on the side and kept in a cool place, under cover from sun and rain, until put into the cellar or sent to market. A dry cellar, that can be kept as near as possible at a temperature just above freezing, is an excellent place in which to keep apples through the winter.

Thus it will be seen that, in order to secure a good crop of profitable apples, there must be care, watchfulness, labor and judgment exercised from the first preparation of the ground for planting to the final disposition of the fruit; and so the motto of this essay shall be: "The price of good fruit is eternal vigilance."

Mr. Arnold's New Grapes.

The following opinion of these grapes by the Rev. Henry Ward Beecher, who is a thorough judge of fruit, will probably interest some of our readers.

"The box containing five varieties of grapes and two of raspberries came safely, with the fruit in excellent condition. Accept my thanks for your kindness.

"I have duly and properly examined the specimens, and am much pleased with the whole lot.

"The raspberries, for fall bearers, must be valuable. The yellow is not inferior to the Brinckle's Orange in sprightliness, and only a little inferior in richness. The red, too, is tender and juicy.

"Of the grapes I find No. 2, *Cornucopia*, hardly ripe enough, I imagine, to disclose its full merit, slightly foxy, pulp tending to break up in the mouth. I should think good wine could be made of it.

"No. 1, Othello, is good, with just a nice trace of mild flavour, solid meat, or jelly-like, but sweet skin.

"No. 16, Canada. This is a really good grape, melting, sprightly and sweet—I should have said good enough, if you had not sent with it No. 8, Brant, which I think the best coloured grape of the five, and as good a grape as one should desire. The pulp has nearly disappeared in this, and juice takes its place. I can easily imagine that one might strive in vain to choose between 8 and 16, and at last end in taking both.

"No. 5, the White Grape (Antuchon) has unmistakable Chasselas blood in it, and as tender (if I remember Chasselas aright), a sub-acid dash in it—a mere suggestion of sour, which I think finer than Chasselas.

"Judging simply from the specimens sent, if I were shut up to the choice of one, I would take No. 8, but on the express condition that No. 5 should go with it.

"I regard all of them as decided acquisitions, but Nos. 8, 16 and 5 as great horticultural treasures."

New York State Grape Growers' Exhibition.

We extract the following account of the New York Grape Show, of which we have previously given intimations, from the *Boston Cultivator*:—

"The first Annual Exhibition of the New York State Grape Growers' Association, held at Canandaigua on the 7th and 8th of October, was pronounced by distinguished horticulturists the finest show of grapes ever witnessed in this country. We have never before made as large a collection of varieties, and kinds that heretofore have only scantily appeared on exhibition tables, were here in profusion. Eighty-one exhibitors spread their collections on the ample tables, and, including seedlings and a few kinds of hot-house grapes, the varieties numbered something more than one hundred. Judged by this Exhibition, New York would be placed in the front rank of grape-growing States, a position she justly merits, not only by reason of the extent of vine culture within her borders, but for the uniform health and high productiveness of the grape in the same limits. Also in the manufacture of those important products of the

grape, wine and brandy, high excellence has been attained. Both sparkling and still wines and brandies, made in New York cellars from New York grapes, challenge, with unvarying success, those from any other part of our country. And grape culture in this State, as elsewhere in the Union, has but begun. And varieties that are hardy, early and excellent, render it possible to grow grapes in localities heretofore deemed unsuitable. The culture will rapidly widen. One of the most cheerful features of grape culture, made prominent by this Exhibition, is the exemption of the vine and its fruit from serious disease in this State. There is some mildew, but no rot. Frost is the most dangerous enemy.

Among the numerous distinguished horticulturists present, we noticed Hon. Marshall P. Wilder, of Boston; E. S. Rogers, Salem, Mass.; Dr. John A. Warder, Ohio; Patrick Barry, Chas. Downing, Dr. Grant, and A. S. Fuller, New York.

The display of the newer varieties and Seedlings was very interesting. Mr. Arnold, Paris, Canada, sent five or six numbers of his series of hybrids. They are claimed to be a cross between the Clinton and Black Hamburg, and the vines are said to be hardy, and the fruit was sprightly and agreeable. The Lorain grape was shown by Barney & Carlin, of Sandusky, Ohio. This is a white or amber grape, sweet to the taste and handsome to the eye, and a supposed cross between the Isabella and Catawba. Dr. Underhill, of Croton Point, N. Y., exhibited three new seedlings, hybrids, one a cross between the Concord and Black Humburg; another between the Concord and Black St. Peters, and the third between the Delaware and a foreign variety. These bore off the first and second premiums for seedlings. Nothing in this line attracted more attention than the "Eumelan," Dr. Grant's newest grape, which he is pushing into notice. It is a black, early variety, and said to be of better quality than the Israella."

A number of other seedlings are mentioned. Among the exhibitors, Messrs. Ellwanger and Barry showed a collection of fifty varieties, the largest number sent by any single firm or exhibitor. Altogether, the Exhibition was very successful, and will, no doubt, do much to stimulate grape-growing in the country.

The Apiary.

The Honey Season in the United States.

The long drought with which our neighbours in common with ourselves have been afflicted, joined to other peculiarities of the season, has seriously affected the quantity of honey made, and left many stocks apparently insufficiently provided for the coming winter. In reference to this subject Mrs. Ellen S. Tupper says:—

From all quarters come reports of an utter failure of honey the past season. In some places bees that did not swarm have not made enough for winter subsistence—while some that did swarm have starved, and the swarm has perished.

In Southern Illinois—usually one of the best regions for bees—no honey has been stored. In this section the spring was so cold and backward that the bees did nothing until the 16th of June—all my colonies lost in weight until then. From the 15th of June until the 10th of July they gathered faster than I ever knew them to do. From Alsike clover, white clover, and linn, the yield of honey was abundant. All strong colonies in that period of time filled their hives and stored some in boxes—but since then they have barely held their own. Not a colony in my apiary has failed to store enough for winter, and the few now colonies that were made in June have all filled their hives—but surplus honey they have not stored to any amount; I think they have not averaged more than ten lbs. to each hive.

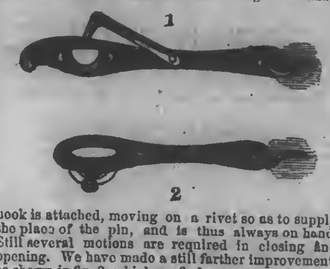
"From different sources the inquiry comes, 'What shall we do with the bees that have not enough to live on? and how can we guard against such a state of things in future?'

The first question each bee-keeper must decide for himself in view of the condition of his own bees and his wish for the future. If it is possible in any case to make one good strong colony out of two or three weak ones, it is the best policy always to unite them. I fear there are cases this year where this can not be done. Bees may be fed on a syrup made of sugar and water with safety; they have been wintered on this and on sugar candy when they had not a pound of honey. To do this to advantage it is best to begin at once. They do better to be fed now than in the winter. Give them constantly all the syrup they will take up from now until near winter weather, then protect them properly, and in spring give them more aid or not as as they need. Colonies that have half enough to winter on should specially be fed. It is poor economy indeed to leave them until starving before you aid them. Give them the syrup through the pleasant fall weather, and they will go into winter in better condition. Whatever course you may take *don't let any bees starve.* If you will not feed them yourself, give or sell them to others who will."

Miscellaneous.

A Convenient Hasp.

Every door which is often used should be furnished with a good self-fastening latch, but it sometimes happens that on outbuildings, which are less frequently visited, and which must be secured with a padlock at night, a common hasp is regarded as sufficient. Often the single strap is placed over the staple, and during the day time is fastened to its place by a small wooden pin, and not unfrequently with a corn cob. Serveral motions must of course be made every time the door is opened, and when it is closed again. Sometimes the pin is lost, and then a search must be made for a stick or broken limb of a tree to supply its place. To obviate this inconvenience a hasp has been contrived and much introduced into use, like that show in fig. 1. A small



hook is attached, moving on a rivet so as to supply the place of the pin, and is thus always on hand. Still several motions are required in closing and opening. We have made a still farther improvement, as shown in fig. 2, which we find a great convenience, and which may be fastened and unfastened almost as readily as the best latch. A projection is made on the lower side, as distinctly shown by the figure, which is dropped into the staple, and holds the door securely. Another staple is placed on the opposite side of the hinges, by which it is as readily fastened open. At night the loop is slipped on the staple and secured by a padlock. This hasp will do for doors that are frequently used or passed many times in a day.—*Country Gent.*

☞ An indignant orator at a lively political meeting, in refuting an opponent, thundered:—"Mr. Chairman, I scorn the allegation, and I defy the alligator."

☞ A small child being asked by her Sunday school teacher, "What did the Israelites do after they had crossed the Red Sea?" answered; "I don't know, ma'am, but I guess they dried themselves."

☞ The annual importation of tobacco into England is fifty millions of pounds. Would it not be better, asks the *Public Health*, if the millions of acres now covered with the tobacco plant were producing cereals, tea, coffee, and cocoa, and thus our food cheapened and our poor better fed?

The Best Things.—The best thing to give your enemy is forgiveness; to give your opponent, tolerance; to a friend, your heart; to your child, a good example; to a father, deference; to your mother, conduct that will make her proud of you; to yourself, respect; to all men, charity.

All Work and No Play.—A clergyman who enjoyed the substantial benefits of a fine farm, was slightly taken down on one occasion by his Irish ploughman, who was sitting on his plough in the wheat field. The reverend gentleman being an economist, said with great seriousness: "John, wouldn't it be a good plan for you to have a stub scythe here and be cutting a few bushes along the fence while the horses are resting a short time?" John, with quite as serious a countenance as the divine himself, said: "See here, wouldn't it be well, sir, for you to have a tub of potatoes in the pulpit, and while they are singing, to peel 'em awhile to be ready for the pot?" The reverend gentleman laughed heartily and left.

PATENTED April 13th, 1867.

THE cheapest and simplest constructed Fork in use in the Dominion of Canada. County or Township Rights for the manufacture of the above Fork may be obtained from the undersigned. JAMES W. MANN,

v4-20-tf Port Dover, Ont.

Markets.

Toronto Markets.

CANADA "FARMER" Office, Oct. 29th, 1868.

FLOUR AND MEAL.

Flour—The market has been very dull, and though no decided decline in prices can be reported, there has been a want of firmness in the market. The demand for No. 1 Super is very limited. We quote the wholesale prices:—Flour, No. 1 super, $5 10; do. Fancy, $5 35; do. extra, $5 50; do. superior, none. *Oatmeal*, $5; *Cornmeal*, $4.

GRAIN.

Wheat—The market is quiet and dull; spring wheat has been offering freely at $1 12 to $1 14. On the street market the receipts are very light—only 4 few loads come in daily. Street prices range from $1 10 to $1 12 for spring; $1 25 to $1 35 for fall; and $1 14 to $1 15 for midge-proof.

Oats—The market is firm and advancing. Holders now ask 52c. to 53c. for car lots. On the street market 55c. is the ruling price.

Barley—The market has been weak and irregular since our last report, rising and falling in sympathy with Oswego. In general buyers would not offer over $1 35. Holders were asking $1 40. There is at present in store in the warehouses here 145,000 bushels. On the street market only a few loads are now daily brought in. Prices range from $1 38 to $1 40.

Peas—The market is quiet and dull. There were no buyers at over 90c. On the street 90c. is the price.

HAY AND STRAW.

Only a limited supply has come into market, and prices have in consequence somewhat advanced. *Hay* has been selling at from $14 to $18. *Straw*, at from $7 to $11 50.

PROVISIONS.

Dressed Hogs—Coming in freely for the season. The receipts are daily increasing, the high prices of feed making farmers anxious to get rid of their stock as soon as possible. Once the cold weather sets in, it is anticipated that there will be quite a rush on the market. There was a perceptible improvement in the quality of the hogs offering this week over those of last, and an advance in prices has taken place, especially to heavy hogs. Selling off the cars at $6 25 to $6 50; choice heavy lots from farmers would bring $7 to $7 25.

Butter—The business between dealers is gradually lessening now the sharp frosts have cut short the make. We quote common to fair at 19c. to 21c.; fair to good at 21c. to 22c.; choice dairy at 22c. to 24c.

Eggs—The shipping business in eggs for the season is about exhausted. 17c. to 19c. was paid this week.

Bacon—Rather more active in the market. Cumberland cut offering at 11c.; some small sales taking place at that price. There are some enquiries for Liverpool account. A good demand is looked for during the next two months for the English market.

Pork—Very light stocks in the market. Held firm at $24 75 to $25. Chicago mess cannot be laid down here at the above figures. The small stock in this market is principally Chicago.

Lard—In good demand and steady at 15c. The high price of butter tends to keep the market firm.

Cheese—The market continues dull, but the week closes with an improving tendency. The late rise in the English markets has given dealers more confidence. Prices are somewhat firmer. A lot of 100 boxes sold yesterday at 11½c. here.

Salt—Market firm, with however less doing than of late. American is unchanged. Liverpool coarse is worth $1 30 to $1 40. Goderich sells at $1 80.

Potatoes—Are scarce and in demand. Prices have advanced about 10c. during the week, and now stand at 75c. to 80c. per bushel.

THE CATTLE MARKET.

The market has been very active. There has been quite a large attendance of drovers, and competition was brisk. 1st class cattle find ready sale at $6 to $6 50c. per 100 lbs., dressed weight.

There was a large supply of sheep and lambs in the market yesterday. The principal owner was P. Seagrave, drover. He had a drove of 300 head which were purchased in Scott and Maripoes, and sold at prices varying from $2 to $5 each.

Pork—The general range for good hogs has been from $5 12½c. to $5 50c. A great many of the lots offering are poorly fatted, and would not command even the lowest price.

Wool.—There has been a fair business doing in wool, principally, however, in small lots. Canada combing wools are now very scarce in the New York and Boston markets, and holders are getting in these markets the extraordinary high price of 75c. per lb. for all they can supply. It is said that so great is the scarcity of this grade of our wool in the New England States, that many of the mills there which are dependent on us for their supplies have lately been working half time, on account of the difficulty of procuring material. Ordinary pulled wool sells here at from 26c. to 27c.

Hides and Skins—Hides, green, rough per lb., 5½c.; do. green inspected, 7c.; do. cured and inspected, 7½c. to 8½c. Calfskins, green, 10c.; do. cured, 12c.; do. dry, 18c. to 20c. Lambskins, green, 45c. to 50c.; Sheepskins, 60c.

Montreal Markets.—Oct. 28.—*Flour*—Superior Extra, $7; Extra, $6 25c. to $6 50c.; Fancy, $5 87½c. to $6 05c.; Welland Canal Superfine, $5 20c. to $5 21½c.; Superfine No. 1 Canada Wheat, $5 20c. to $5 45c.; No. 1 Western Wheat, $5 22½c.; No. 2 do. $4 90c. to $5.; Fine, $4 25c. to $4 40c.; Middlings, $3 90c. to $4; Pollards $3 to $3 25c. *Wheat*—Canada Fall, $1 30c.; Spring, $1 20c.; Western, $1 20c. to $1 22½c. Peas—Per 66 lbs., $2 lbs. 50c. *Barley*—Per 48 lbs., $1 30c. to $1 35c. *Butter*—Dairy, 21c. to 23½c.; Store-packed, 19c. to 21½c. *Cheese*—Factory 10c. to 11c.; Dairy, 9c. to 10c. *Peas*—$1 10c.

New York Produce Market.—*Flour*—Dull and heavy; receipts, 23,000 barrels; sales, 6,900 barrels, at $6 to $6 60c. for superior State and western; $6 65c. to $7 20c., for common to choice extra State; $6 55c. to $7 75c. for common to choice extra western. *Rye Flour*—Heavy, at $6 to $7 00c. *Wheat*—Dull; receipts, 72,000 bushels; sales, 43,000 bushels, at $1 60c. to $1 55½c. for No. 2 spring; $2 60c. for white State and Michigan. *Rye*—Quiet. *Corn*—Dull; receipts, 15,000 bushels; sales, 39,000 bushels, at $1 09c. to $1 10c. for unsound, and $1 11c. to $1 12c. for sound mixed Western afloat; do. $1 12c. in store. *Barley*—Decidedly lower; receipts, 19,000 bushels; sales, 3,000 bushels Canada West, at $2 20c. *Oats*—Lower; receipts, 50,000 bushels; sales, 87,000 bushels, at 71½c. to 72c. for new Western. *Pork*—Firm at $25 75c. to $28 50c. for mess; $22 25c. for old. *Lard*—Easier at 15½c. to 17½c. for steam; 17½c. to 17¾c. for kettle rendered.

Chicago Markets, Oct. 28, noon.—William Young & Co.'s report.—Wheat—Receipts, 103,000 bus.; shipments, 40,000 bus.; No. 2 wheat dull at $1 13½c.; Corn dull at 78¾c; receipts, 45,000; shipments 48,000. Pork nominal, unchanged.

CATTLE.

CLASS V.—THE PRINCE OF WALES' PRIZE.—(14 ENTRIES.)

JUDGES.—J. Ashworth, Scarboro; J. P. Wheeler, Ottawa; Thos. McCrae, Guelph; Charles J Buckland, Guelph; John J. Weir, jr., West Flamboro'; John Dew, West York; L. F. Allen, Buffalo, N. Y.

The best herd of thorough-bred cattle, of any pure breed, consisting of one bull and five females, of any age or ages—Prize presented by His Royal Highness the Prince of Wales—M. H. Cochrane, Compton, Durhams	$60
2nd do by the Association, John Miller, Pickering, Durhams	40
3rd do do F. W. Stone, Guelph, Durhams	20
F. W. Stone, do Herefords, highly commended.	
M. H. Cochrane, Compton, Herefords, highly commended.	
Wm. Hood, Guelph, Galloways, highly commended.	

REMARKS BY JUDGES.—In relation to the awards made in the herd class, the judges have found great difficulty in coming to an accurate conclusion as to the superior merits of the herds submitted to their inspection, on account of the different breeds of animals competing on equal terms with each other. Three breeds were submitted, viz:—Short-horns, Herefords and Galloways, each of them possessing certain eminent and valuable qualities. Such diverse breeds should never be submitted on equal terms for prizes. Each is valuable for certain soils and surfaces of our country. The Short-horns are, beyond question, the most popular, and probably the best breed of cattle with the majority of our stock breeders and graziers. In some districts of country where they prove inferior to the Herefords or Galloways. So with either of the latter breeds each of them the best of their kind. Suffice it to say that we have given our awards under most embarrassing circumstances, we would have hesitated to act on this committee. Under the circumstances, we beg leave, with all due respect to the judgment of the managers of the Board of Agriculture, to suggest that prizes be offered hereafter for the best herd in each of several classes, and that each breed be exhibited separately by themselves, under whatever name they may be recognized. Under permission of the rules of the Board, the Committee, satisfied of the superior excellence of two herds of Herefords submitted to their inspection, would award them as if in a class by themselves, both of equal merit. Also, the Galloway herd, as of fine quality and finish.

CLASS VI.—DURHAMS.—(127 ENTRIES.)

JUDGES.—Prof. Howard, Lansing, Mich.; Prof. M. Miles, Lansing, Mich; G. S. Shaw, Darlington; John Dew, West York; G. Z. Rykert, St. Catharines.

AGRICULTURAL PRODUCTIONS.

CLASS XXVII.—GRAINS, SMALL FIELD SEEDS, HOPS, &c.—(462 ENTRIES.)

JUDGES.—John Laurie, Fort Dalhousie; P. R. Palmer, Thurlow; A. Cooke,——; John McKay, Toronto; P. M. Shannon, Rimalyon; S. J. Pearson, Meadowvale.

'The Canada Company's prize for the best 25 bushels of Fall Wheat, the produce of the Province of Ontario, being the growth of the year 1868. Each sample must be of one distinct variety, pure and unmixed, of the best quality for seed, and not to be tested merely by weight. The prize to be awarded to the actual grower only of the Wheat, which is to be given up to and become the property of the Association, for distribution to the County Societies for seed—John Hamilton, Strabane $100

2nd do G. L. Beardmore, Toronto 2
Best upper leather, grained, two sides, Bowman & Zinkin, Woolwich 3
2nd do W. H. Lingwood, Nichol 2

EXTRA ENTRIES.

J. W. Barry & Son, Bradford, assortment trunkmakers, bookbinders, druggists and glovers' skins ..... Diploma.
H. Ferdinand, Waterloo, three oil dressed calf skins.. Highly commended
W. H. Lingwood, Nichol, buffed cow and splits ..... Commended
T. Manning, Strathroy, boot and shoe tip ..... Commended
Bowman & Zinkin, Woolwich, pebbled cow hide 2
Do do buff do 2
Do do satin calfskin ..... Diploma
F. Belgrnai, Hamilton, carpet, cloth, and velvet slippers... 3

CLASS LII.—WOOLLEN, FLAX, AND COTTON GOODS, FURS, AND WEARING APPAREL.—(133 ENTRIES.)

JUDGES—Wm. McMaster, Newmarket; Jno. Rankin, Dundas.

Best one dozen cotton bags, Young, Law & Co., Hamilton.. $4
Best one pair woollen blankets, Empire Woollen Mills, Columbus 6
2nd do R. Ellis, Ancaster 4
D. Clark, Puslinch ..... Highly commended
Best one piece unbleached calico, Young, Law & Co., Hamilton 6
Best one piece woollen carpet, J. W. Vandusen, Grimsby, Highly commended.
Best one piece rag carpet, D. Davis, St. Catharines 5
2nd do Samuel Harvey, Hamilton 3
Best piece fulled cloth, 2nd do, J. W. Vandusen, Grimsby, 4
Best two counterpanes, J. McGregor, Nelson 5
Best assortment of cordage and twines from Canadian flax or hemp, E. Law, Kingston 10
Best drawers, factory-made, woollen, six pairs, Armstrong, McCrae & Co., Guelph 5
Best flannel, factory-made, one piece, R. Ellis, Ancaster.. 5
2nd do Bath Bros. Sheard & Co., Ramsay 3
Best flannel, not factory-made, one piece, J. D. Vandusen, Grimsby 5
2nd do J. McCormick, Ancaster 3
3rd do Wm. Thompson, Beverly ....Highly commended.
Best flannel, scarlet, one piece, R. Ellis, Ancaster 5
2nd do Charles Bradley, Haldimand 3
Best fur sleigh robes, not less than three kinds, H. Ferdinand, Waterloo 8
Best gloves and mits of any leather, an assortment, Hall & Childs, Brockville ..... Diploma and 5
2nd do H. Ferdinand, Waterloo 3
Best Shawls, home-made, Mrs. P. Hiamen, Haldimand 4
2nd do Mrs. J. R. Hess, Barton 2
3rd do H. M. Switzer, Palermo ..... Commended.
Sheepskin mats, dressed and colored, an assortment, J. Clench, Hamilton 6
2nd do J. W. Barry & Son, Bradford 4
Best shirts, factory-made, three of each, woollen and Angola, Armstrong, McCrae & Co., Guelph 5
Best stockings and socks, factory-made, woollen, three pairs each, Armstrong, McCrae & Co., Guelph 4
Best suit of clothes of Canadian cloth, F. G. Furnivall, Hamilton 5
2nd do Lawson Bros., Hamilton 3
Best Wincey, checked, one piece, J. McCormick, Ancaster.. 3
Best Woollen shawls, stockings, drawers, shirts and mits, an assortment, D. Clark, Puslich 10
Best yarn, white and dyed, one pound of each, Armstrong, McCrae & Co., Guelph 3
2nd do J. W. Vandusen, Grimsby 2
2nd do D. Shaver, Ancaster ..... Highly commended
Best yarn, fleecy woollen, for knitting, one pound, Armstrong, McCrae & Co., Guelph 3
2nd do J. Richardson, Pelham 2
Best yarn, cotton, two lbs., Young, Law & Co., Hamilton.. 3
Best yarn, linen, two lbs., E. Law, Kingston 2

EXTRA ENTRIES.

E. Law, Kingston, tarred cordage ..... Highly commended.
T. Thomson, Williamsburg, Scotch plaid ..... Highly commended.
Mrs. J. Grant, Puslinch, home-made woollen plaid ..... Highly commended.
P. Wilson Eramuss, home-made wincey 3
C. Foster, East Flamboro', woollen plaid 2
Lawson Bros., Hamilton, suit of silk mixture, imported goods 2
D. Davis, St. Catharines, balmoral skirting, wincey ...Commended.
R. Ellis, Ancaster, fancy flannel ..... Commended.
Geo. Copeland, Hamilton, Russian hemp rope and cordage. 3
do do do Manilla hemp rope 2
do do do Russian jute hemp rope 2
Armstrong & McCrae, Guelph, lacrosse shirts and stockings. Com.
J. Simpson, Toronto, silk quilt 1
J. Otway, Toronto, six mats ..... Commended.
J. Cook, Toronto, 2 sleigh robes 4
Do. 1 sheep skin 2
J. Richardson, Pelham, wincey plaids ..... Highly commended.
R. Hill, Hamilton, one counterpane 3
James Adams, Toronto, set of military flags, embroidered in silk 4
Ontario Cotton Warp Mills, Thorold, cotton yarn dressed on the beam 3
Ontario Cotton Warp Mills, cotton batting 1

The Field.

A Good Crop of Turnips.

To the Editor of THE CANADA FARMER:

SIR,—I send you some statements in the CANADA FARMER of very large yields of turnips. I think it not amiss to send you the weight of seven greystone turnips pulled to-day, from a field on the farm of Mr. A. A. Brodie, Gladstone.

No. 1, 20 lbs.; 2, 15½ lbs.; 3, 16½ lbs.; 4, 14½ lbs.; 5, 14½ lbs.; 6, 14½ lbs.; 7, 12½ lbs.—108½ lbs.—nearly averaging sixteen pounds apiece. A pound of seed was sown, and the crop is equal, although these seven roots were to appearance the largest met with in pulling.

Whether these would be considered large or not, by those acquainted with the growth of greystones, I do not know—perhaps some of the readers of the CANADA FARMER can tell. The ground was in corn last year, was manured previous to planting the corn, but received no manure for the turnips. In the same field there are two acres of excellent yellow Aberdeens—the rest of the field being Skirving's improved purple-top Swede—all unusually large and well-formed bulbs.

GLADSTONE, Nov. 7, 1868.

Pasturing New Seeded Fields.

THERE are some cases where it will do to pasture new seeding. With a good growing season, when the clover and grass is up so that some is cut by the reaper, and there is a vigorous growth after harvest, there is no harm in pasturing moderately. Then considerable feed may be had without injuring subsequent crops. Indeed I have seen new seeded clover injured by getting too forward the first Fall. The crop was never so good afterwards. If the clover had been fed off, there is little doubt that the crop would have been heavy the next season. But such cases are rarely seen. It is only when clover very generally comes into blossom that it may be injured in this way. Vastly more is injured by feeding down too close.

In dry seasons, when land is none too well seeded, and the young clover and grass have made but a small growth at best, it is a losing practice to pasture new seeding. The young plants need all of their life and vigor to stand the heat and drouth, and to make a sufficient growth; while they need all the growth and strength of root that can be secured to stand the Winter and Spring, and make a good crop next season. The root will be in proportion to the top. When fed off, there is much less growth of root—the efforts of the plant being directed to secure a proper proportion of leaves, on which the general growth of the whole plant so largely depends. If these leaves are closely fed off during the Fall, little gain in size and strength is secured. Then the root has but little hold on the soil, and in freezing and thawing weather is easily thrown out.

There is a good deal lost in this way. The small growth affords but little pasture at the best, while succeeding crops are often seriously injured. Many dollars are thus lost for every dollar's worth of feed obtained. Few are aware or stop to consider how much is lost in this way. With a good seeding, and fine growth after harvest, considerable pasture is secured without any apparent injury to succeeding crops. So they expect to feed off all stubbles, and the next season, if the crop is light, it is attributed to some other cause, or there is much wonder and surprise that it is no better. Frequent cases of this kind have come under my observation, and repeated trials have shown that a small growth, when not fed off the first Fall, will give a much better crop the next year. —*Cor. Country Gentleman.*

☞ Muck, says an exchange, should never be taken to the field direct from the swamps. It should be exposed to the atmosphere for six months or more, the longer the better, and composted with lime or unleached ashes.

☞ A correspondent of the *Journal of Agriculture* says he finds his clay-loam grounds increase more in productiveness by the use of eight bushels of salt to one bushel of plaster per acre, than from the application of barn-yard manure.

How to Foretell the Weather.

To the Editor of THE CANADA FARMER:

SIR, the following mode of foretelling the weather, which I have taken from an English paper, is worthy of consideration and observation here, though, of course, the same rule may not hold good on this side of the Atlantic. The other day I could not help overhearing in a railway carriage an amusing instance of judging the weather by experience. A gentleman, who was on his way to attend the annual dinner of the Canadian Loyalists, at Grimsby, said to his companion, in reply to some observation on the weather, that he was sure it would not rain that day, it never did on the 13th of October. On being asked the grounds of his opinion, he replied that he had attended the Grimsby dinner for twenty-one years, and he had never known it to rain on that day, and therefore he did not believe it would. This year his faith must have been shaken, as rain it did, in spite of the dinner, steadily, quietly, the whole afternoon.

The account I referred to is as follows:—"The late Marshal Bugeaud, when only a captain, during the Spanish campaign under Napoleon I., once read in a manuscript which by chance fell into his hands, that from observations made in England and Florence, during a period of fifty years, the following law respecting the weather had been proved to hold true:—'Eleven times out of twelve the weather remains the same during the whole moon as it is on the fifth day, if it continues unchanged over the sixth day; and nine times out of twelve like the fourth day, if the sixth resembles the fourth.' From 1815 to 1830 M. Bugeaud devoted his attention to agriculture, and, guided by the law first mentioned, avoided the losses in hay-time and vintage which many of his neighbours experienced. When Governor of Algiers, he never entered on a campaign till after the sixth day of the moon. His neighbours at Excideuil, and his lieutenants at Algeria, would often exclaim, 'How lucky he is in the weather!' What they regarded as mere chance was the result of observation. In counting the fourth and sixth days he was particular in beginning from the exact time of the new moon, and added three-quarters of an hour for each day for the greater length of the lunar as compared with the solar days.

This may possibly interest some of your readers. I have not yet had time to test the rule myself.

LUNA.

STANDARD WEIGHT OF THE BUSHEL—CORRECTION.—We regret to find that by a typographical error the standard weight of the bushel of corn was set down in our issue of October 15th at 58 lbs. It should be 56 lbs.

TUMOURS.—A subscriber from Ancaster writes: "Some of my cattle, and others belonging to my neighbours, are troubled with tumours growing on their neck and cheek, varying in size from a hen's egg to a cocoa nut. Sometimes they discharge and heal up, while others grow up afresh, and thus continue for months. If you can tell the cause, and the treatment they ought to receive, you will much oblige."

ANS.—Small tumours in the region of the head and neck are frequently successfully treated by the application of iodine ointment, in the proportion of one part of iodine to six parts of lard. When these tumours appear to contain matter, they should be opened freely, and dressed with diluted carbolic acid. Our correspondent mentions having sent a previous communication on the same subject, but the above is the only one that has reached us.

MUSKOKA.—"F. ..." "I understand ... ka district, and that being the case, is it possible to make a good wheat and grain-raising country of it, without spending more on super-phosphates than could be realized from the crops? Also, what crops would do best on such a soil?"

ANS.—There are many parts of the older settled portions of the Province that are destitute of limestone, and yet have proved themselves excellent wheat-growing districts. Much of the land in Muskoka seen by tourists, in the immediate neighbourhood of the lakes, is rocky and barren, but there are tracts of excellent soil, well calculated to produce any of the ordinary crops of the country. We have seen good samples of all the common cereals, field roots and garden vegetables, including melons, that were grown in Muskoka.

COAL TAR A SUBSTITUTE FOR PAINT.—William McDougall, of Baltimore, writes:—"In the January number of *Chambers' Journal*, the article on science and arts recommends coal tar instead of oil paint as a preventive of iron from rust. Could you inform me how the tar is prepared, or is it applied as it is, raw? I want it for painting sheet iron for roofing a large steam saw mill."

ANS. Coal tar is extensively used in coating iron articles of hardware, and is applied by heating the coal tar over a stove, which gives it a thinner consistence, and using a stiff brush to lay it on. Or the article to be coated is sometimes heated and dipped into the coal tar. Naptha is occasionally mixed with the tar to reduce it, make it dry more quickly, and give a degree of polish to the surface.

TO CORRESPONDENTS.—The insertion of the Prize List has so curtailed our space for other matter, that we are compelled to defer several communications, which shall, however, receive our earliest attention.

The Canada Farmer.

TORONTO, CANADA, NOVEMBER 16, 1868.

NEW SERIES

OF

The Canada Farmer.

TWO MORE issues will complete the FIFTH VOLUME of this journal; and we are justified by the unanimous voice of those best able to judge in our own Province, and by the constant laudations of our cotemporaries in Great Britain and the United States, in claiming that the task we undertook five years ago has been spiritedly and successfully accomplished. We but echo the general voice, when we claim that for the care and skill with which its reading matter has been written and selected, for the suitability of its fortnightly contents to advance the agricultural knowledge and system of the Province, for the beauty and profuseness of its original illustrations, and for the creditable style in which the Typography of the work has been executed, the farmers of this Dominion have had in THE CANADA FARMER a journal devoted to their interests unsurpassed by any other country.

The publication of THE CANADA FARMER was not undertaken in the expectation that a great profit would accrue from it to the proprietors. It was commenced with the view of ... ratum in a country so ... on its farming interests, and to ... excellence of Agriculture throughout the Province. But the confident belief ... tained, that a really efficient Journal would rally around it the cordial, and united, and generous support of the whole farming community. Our part of the work has been performed in a style of which we feel we are entitled to be proud. But that ample support which we expected to receive at the hands of the farmers has not been accorded. It is true that the circulation of THE CANADA FARMER has always been vastly larger than any other agricultural publication ever received in Canada; but the labour, and expense, and enterprize devoted to it have been far in advance of any other similar publication. We have spared no expense in keeping up the character of the journal—we have kept down the number of advertisements, so that the reading matter might not be lessened—and to aid the operations of the Township and County Societies, we furnished the paper to them at a rate which ought to have placed on our subscription-list the name of every man in Upper Canada pretending to be a farmer. But the lamentable facts are before us, that not one farmer in ten has subscribed for the paper,—and that no profit has accrued from its publication. The slightest effort put forth by the prominent farmers of each Township would have secured a circulation vastly in advance of what it has been, would have given us some compensation for our labour, and enabled us to increase from year to year the size and attractions of the journal.

Notwithstanding all this, the publication of THE CANADA FARMER might have gone on without change, for years to come—as a labour of love—but for the Postal Bill of last session. This measure has, however, totally changed the position of matters. Heretofore, all agricultural newspapers have passed through the Post Office *free of postage;* but, from and after the first day of January next, a postage rate of one cent per copy is to be imposed upon them; and this not payable by the reader of the paper, but payable by the publisher in advance. The effect of this most arbitrary and absurd regulation—and which, so far as we know, strikes only at THE CANADA FARMER and one other publication—is to compel us to pay the Post Office authorities, in advance, no less a sum than $1,680 *per annum*. This we cannot do, and continue to issue such a sheet as we have done, at the very low rates we have heretofore submitted to.

Under these circumstances, we have resolved to commence on the 1st of January, 1869, a new series of THE CANADA FARMER. We propose to issue it monthly instead of semi-monthly; but each copy to contain as much matter as two copies now do. We propose to increase, if possible, the interest and usefulness of the paper, and to add fresh attractions to its columns. But we propose, at the same time, that the price hereafter shall be uniformly ONE DOLLAR PER ANNUM, without abatement, leaving us, after payment of postage, 88c. net;—and we make our appeal to the Farmers of Canada, to sustain with a little more energy a paper in their own interest, and one that has done them no discredit, either at home or abroad.

Land Questions in the Ontario Legislature.

The Legislature of Ontario assembled for dispatch of business on the 3d inst., and we are glad to perceive, both from the Governor's Speech and the remarks of members on both sides of the House, during the debate in reference to the address in reply, that there is a disposition to give early attention to those important land questions, the adjustment of which is so imperatively demanded by the best interests of the country. It is very generally conceded that the legislation on these questions during the first session of our Provincial parliament was far from satisfactory. Men of all parties join in condemning it as narrow, illiberal, unsuited to our wants, behind the age, and but ill calculated to attract what most of all we want, an industrious, energetic, thrifty agricultural population. If the legislation of last session was unsatisfactory, the procedure of the Crown Land Department during the recess has been still more so. A summary notice was issued in June last requiring immediate payment of arrears by settlers on lands purchased from the Government. Believing themselves threatened with the loss of their farms, not a few hastily sold them for what they would fetch, and others borrowed money at high interest to keep them out of the clutches of the Commissioner, while the rest, in painful suspense, awaited their fate. The time for payment was extended until October, at the earnest representation of influential people resident in the sections affected by the demand for arrears, and has been further extended until March. The feeling is very generally entertained by intelligent men of all shades of politics, that the greatest leniency should be shown toward settlers in arrears, and anything like indiscriminate coercion, or forfeiture of land, should not be thought of for a moment. Indeed, no man, unless possessed by the spirit of a Shylock, would think of exaction on pain of confiscation, and we are persuaded the Crown Land Commissioner never seriously entertained the idea of doing what he threatened. It was, therefore, very unfortunate, to say the least of it, that the settlers should have been thrown into panic, and put to trouble and loss. From what has transpired in the Legislature, we hope assurance will soon be conveyed to the parties concerned that they will not be disturbed or put to further unnecessary annoyance about their land arrearages. Except in the case of men of intemperate and otherwise loose character, the anxiety of a settler to get his land free from encumbrance will be a constant stimulus to effort in the direction of paying up. It is the great ambition of this class of people to own their farms, and they may, generally speaking, be relied upon to constitute themselves proprietors at the earliest possible date. When the toils of clearing land and getting in the first crops are considered, and account is taken of the many difficulties and hardships encountered by settlers in new townships; when further it is remembered that they are adding largely to the wealth of the country by their labours, assuredly every indulgence ought to be extended to them at all consistent with the public interest. Being a rich Province, with a million of money at our credit, we do not need to push honest and well-intending debtors.

The free land system is to be improved. This is well, for it greatly needs improvement. A larger grant is contemplated, and on less restrictive conditions. As yet we have not come up to the liberality of the United States Government in this particular, and if we wish to arrest and detain a portion of that tide of emigration which sets so strongly toward the far west, we must offer at least as tempting inducements as are held out by our neighbours across the lines to those who are seeking homes in the new world. We see no cause for hesitation in this matter. The faster we can fill up our waste places with an industrious population, the better will it be for every material interest of our country. Every settler becomes at once a producer and a consumer. He is profitable to us in both characters, and we can afford to pay a premium on population, for that is our great want.

We trust that the present session will not close without the enactment of a Homestead Law. Much was said on this point last session, and but little done in regard to it. It is to be hoped this order will be reversed during the present session, and that however little may be said, something substantial will be done. In this respect, again, we compete disadvantageously with Brother Jonathan. Beside this argument based on expediency, there is ample ground for urging a Homestead Law on high and righteous principles. We are by no means in favor of supplying dishonest people with an easy mode of evading their just debts. There is no lack of these things already, and with or without such a law, rogues will always find ways of cheating those who are unfortunate enough to put confidence in them. But a well-framed and wisely guarded Homestead Law is not a premium on dishonesty, but an incentive to industry and energy. The payment of one's debts must always be more a matter of innate honesty than of security and compulsion, and if a Homestead Law induced as one practical effect a wider prevalence of the ready money system of doing business, it would be of incalculable benefit to the country. We have heretofore urged at length the arguments in favour of the law in question, and need do no more at this time than call attention to the matter as one that imperatively demands immediate action on the part of our Legislature.

We trust the Minister of Agriculture will be prepared to submit some measures of importance in connection with his department. Now that we have so large a balance to the public credit is a good time to moot the subject of a model farm and school of agriculture. Not a few of the States of the American Union have richly-endowed institutions of this kind, and we ought not to lag behind in a thing of such manifest importance. Our Provincial exhibitions furnish proof that we are in many respects ahead of our neighbours in the United States. Let us determine that we will equal, and, if possible, excel them in provision for agricultural education.

Book Notices.

"The Carolina Farmer."—We have received "the initial number," as it is fashionable now to call it, of a new monthly magazine, with the above title, and "devoted to the agricultural interests of the two Carolinas." It is neatly printed, and contains a miscellany of useful articles, chiefly selected from other journals of its class. In a short "monthly talk with our farmers," we find warm quarters for stock insisted on as essential to success with animals, and the "antediluvian habit" of exposing them to wintry winds and storms deservedly reprobated. How much more this applies to such a climate as that of Canada! In a paragraph on exchanges, the editor proposes to send *two copies* of his journal to sundry papers not mentioned, and requests them to reciprocate the favour. "One copy," he says, "we wish to clip from, and the other we wish to keep for binding." A good idea. There are no "Southern politics" in this journal, and we cordially welcome it to our exchange list, wishing it all success.

"The Little Corporal."—We have more than once noticed this beautiful juvenile monthly, and now, on the occasion of its appearance in a new dress, we take the opportunity of again commending it to public attention and patronage. The November number is at once protected and bedecked with an attractive-looking cover, which is a great improvement. "*The Little Corporal*" is true to its motto, "fighting against wrong, and for the good, the true, and the beautiful." Its articles are exceedingly well written, and it often contains rare gems of poetry and choice pieces of music. It is published by Alfred L. Sewell, of Chicago, at one dollar per annum, and subscribers ordering now will receive the November and December numbers for the present year in addition to next year's volume.

Hemp and Flax.—A treatise on the culture of these plants has been recently published by Mr. A. Kirkwood, of the Crown Land Department. It contains a vast amount of important information, gathered chiefly from works recently published on the subject in England, and judiciously applied to the circumstances and requirements of Canada. The harvesting of the crops, the manipulation of the fibre, and its application for manufacturing purposes are fully explained. The treatise will be found a valuable work for all who are interested in this important branch of industry.

Agricultural Engineering.—We are glad to learn that a firm have recently arrived from Scotland whose services in one branch of their profession will be particularly useful to agriculturists in this country. Messrs. McDongall and Shaw, Engineers, Surveyors, and Architects, have commenced business in Toronto, and propose to give special attention to the drainage of farm lands, waste lands and towns; and to the improvement of water courses, irrigation of lands and the introduction of water into towns and buildings. They also propose to make a specialty of preparing plans and estimates for the laying out of ornamental and farming properties, for draining fields by tiles and other means, for the erection of farm-steadings and other buildings. We know of few things more needed in Ontario than to have the advice of a professional man of skill and taste, and moderate ideas as to expenditure in such matters. How many beautiful places over our country have been spoiled in appearance by the lack of such advice! How many meditated improvements have been cast aside by a groundless dread of the cost, which one consultation with an experienced professional man might have removed. When work is being done it is sound economy to do it in the most convenient and tasteful way that circumstances and means on hand will permit, and the advice of a skilled professional man is but a small addition to the cost. We hail the introduction of this branch of professional skill amongst us as at once an indication and promise of agricultural progress.

Agricultural Intelligence.

Board of Agriculture.

A meeting of the Board of Agriculture took place in the rooms of the Association on Thursday, Nov. 5th. The President of the Board, the Hon. David Christie, occupied the chair.

A number of communications were read, some of which referred to matters of the past, on which no action could be taken.

The Treasurer's statement submitted showed the total receipts for 1867 to be $82,140 98, including the balance of the previous year. The total amount expended was $75,986 18. A continuation of the report, in conformity with instructions from the Bureau of Agriculture, was read, showing the amount received and expended since last audit.

The communications between the Board of Agriculture and the department at Ottawa, in reference to the cattle disease, were submitted.

A circular, dated Albany, 13th October, was also read, asking a general convention of all interested in the raising of cattle to inaugurate an efficient system of legislation to prevent this and similar diseases. The circular recommended that a convention, with this object, be held at Springfield, Illinois, on Tuesday, the 1st of December—each State to be represented by three commissioners.

At the annual meeting held at Hamilton, Hon. D. Christie, Messrs. Asa Burnham and F. W. Stone were appointed a deputation, and at this meeting it was resolved that the appointments be at once communicated to the Minister of Agriculture for the Dominion, and that he be requested to obtain from the Government compensation to meet the expenses of the deputation.

A number of protests were considered and adjudicated on.

The Secretary reported that he had requested the General Government to pass the prize lists for the exhibition free of postage, but they declined doing so. The prize lists always went free of postage until this year.

A committee was appointed to consider a number of accounts for repairs of buildings at Hamilton.

A letter was read from Mr. Adam Crooks, Vice Chancellor of the University, notifying the Board that the University required possession of so much of the grounds as have been occupied by the Board or its tenant, Mr. Shanly, and that the occupation shall definitely cease on the 30th April, 1869. A committee was appointed to arrange with the University authorities in reference to the matter.

An application was made by Mr. A. Smith, veterinary surgeon, for a grant towards providing a proper dissecting room in connection with the Veterinary College.

The Board granted $150 for the session, provided he furnish the buildings at his own cost.

The Board ordered twenty-five copies of a pamphlet, by Mr. A. Kirkwood, of the Crown Lands Department, Toronto, on Flax Culture. A letter was read from Mr. John A. Donaldson, emigration agent, reporting the state of the flax throughout the country this year. The crop this season, he states, has been quite equal, if not superior, to that of any former year. Having been sown early, the crop got a good start before the drought set in. Lately, he says, there has been quite a demand for the fibre, as well as seed, and the prices realized for both are almost equal to the highest figure realized during the time of the American war.

After the disposal of other matters, the Board adjourned.

The English Harvest of 1868.

The following letter from Mr. Caird to the London *Times* on the subject of the Harvest of Great Britain, will be read with interest on this side of the Atlantic:—

"The publication of the agricultural returns of the United Kingdom affords the basis for an estimate of the yield of the last crop, which, with your permission, I venture to submit for consideration.

The yield of wheat has been ascertained in various parts of the country, and, with the exception of that grown on shallow gravels and light sand, it is pronounced nearly equal to the fine crop of 1864, but not so good as the abundant crop of 1863. It is nearly as much above an average as the crop of 1867 was below it. My own enquiry and observation lead me to the conclusion that thirty-two bushels, or four quarters, an acre may be safely reckoned as the yield of this year, which is five bushels an acre above the yearly average yield of the United Kingdom.

So far we did not need the agricultural returns to help to this conclusion. But without them we could not have known that upwards of 300,000 acres had been added to the breadth under wheat, and that thus, beyond the bountiful yield of each acre, we have this year secured an addition of one-twelfth to the acreage, which is the same thing as an additional month's home supply. The money value of this knowledge may be difficult to estimate. If we reckon its influence on price, at but one shilling a quarter on the total consumption of the country, the cost of obtaining these returns will be repaid to the country one hundred fold.

The cost of imported wheat in the current year will be about £15,500,000. Last year it was £31,000,000. The highest average price of the year was reached in May, 73s. 11d., from which it has fallen in four months to 53s. 7d., or rather over 20s. a quarter. But this saving of £15,500,000 in the price we shall have to pay for foreign wheat will be considerably diminished by the deficiency in the barley and oat crops.

These I reckon to be at least one-fifth below an average crop, and there being likewise a deficiency in the acreage, the ordinary money value of the barley and oat crops of the United Kingdom will this year be probably £10,000,000 under an average. Of this rather over one-half applies to the oat crop, a large portion of which being consumed on the farm, the loss will fall more heavily on the farmer than on the public.

The hay and green crops are also greatly deficient. It would be very difficult to place a money estimate on this deficiency, but the loss of these, which are the basis of stock husbandry and productive corn crops, will seriously trench upon farming capital. A large import of cheap feeding stuffs will be required, for which preparations are already being made in America, where in the valley of the Mississippi the growing crop of Indian corn is said to be unprecedented in abundance. A system of transport has been arranged by the Illinois Central Railroad for the shipment from Cairo to New Orleans of 10,000 quarters daily, in the expectation of orders from Europe at New Orleans to take off this supply.

The potato crop remains to be considered. There is an increase upon it of 80,000 acres—somewhat more than one-twentieth of the whole extent. It will prove an average crop; the second growth, which began after the rains in July and August, having added greatly to the bulk.

On the whole, the harvest of 1868 will prove a productive one of wheat and potatoes—the main food of the bulk of the population, which will thus be supplied at a moderate price. But there will be a great deficiency in the food of live stock, and a very serious loss in that branch of agricultural industry.

JAMES CAIRD."

October 5.

Sale of Mr. Snell's Stock.

To the Editor of The Canada Farmer:

Sir,—I send you a list of the prices obtained for the stock sold at my sale on the 28th, with the names of purchasers in the cattle department. The attendance was not large, but was highly respectable; nearly every man was a "brick." The prices, of course, are not large, but the stock was not in good condition for selling, in consequence of the severe drought of the past summer. Considering that it was the surplus stock of the farm, I think it was on the whole satisfactory. Some of the sheep went to Grand Rapids, Michigan, and to Riviere du Loup, Quebec. The following are the prices the Short Horns brought:

COWS AND HEIFERS.

NAME.	AGE.	OWNER.	
Alma	9 years	R. Craig, Burnhamthorpe	$115
Beatie Bell	10 years	Geo. Anderson, Stanley	150
Bracelet	2 years	Col. Taylor, London	150
Modesty	1 year	Col. Taylor, London	159
Forget-me-not	1 year	T. Porter, Vaughan	98
Helen	4 years	P. O. Martin, Cayuga	101
Fancy	13 years	Col. Taylor, London	145
Peace	4 years	R. Kenny, Ottawa	71
Cora 2nd	12 years	Geo. McGillivray, Whitby	73
Elsie	7 months	P. O. Martin, Cayuga	60
Cantilene	6 months	R. Kenny, Ottawa	72
Wedova	5 months	R. Kenny, "	72
Modora 4th	3 years	Hon. D. Christie, Paris	81

BULLS.

NAME.	AGE.	OWNER.	
Noble Duke	12 months	W. Tindale, Peel	$90
Dixie Duke	6 months	H. Snell, Clinton	147
Lyndon Duke	5 months	T. R. Smith, Waterloo	101
Cameronian	5 months	E. Crawford, Peel Co.	100

Leicester Ewes brought from $12 to $36 a pair; Ewe Lambs, from $14 to $32 a pair. Cotswold Ewes, from $24 to $52 a pair; Ewe Lambs, from $26 to $47 a pair; Rams, from $20 to $60 each. South Down Ewes, $10 a pair; Rams, from $8 to $24 each.

The sale realized $3,264.

JOHN SNELL.

Edmonton, Oct. 30th, 1863.

Immigration Conference.

A conference was held at Ottawa on the 30th Oct., between members of the Dominion and Provincial Governments, on the subject of immigration. A plan of concerted action was agreed on, the details of which are to be prepared in Ottawa and submitted to the Local Governments for their approval. New energy is to be given to the action on the part of the Dominion, by establishing agencies in London and on the Continent—while agencies at all important points in the Dominion are to be maintained. The local Cabinets may supplement the action of the Dominion by sending additional agents to Europe to act in concert with the agents of the Dominion. The immigration policy of each Province must be communicated to the Dominion Cabinet, who will facilitate its diffusion. What is mainly promised from the new system is, that increased energy is to be given to Dominion action, while the Provinces will be left open to do what they please in addition.

A New Branch of Industry.

It affords us much pleasure to know that a new branch of industry has been established in Stratford in connection with the manufacture of flax. Hitherto the article has been prepared for the United States market only to the extent of being scutched. The duties on the other side, however, are levied in such a way as to make it very profitable to carry the process of preparing flax in this country a step further, and heckle it. On scutched flax the duty is $15 per ton. It is also the same on heckled flax. But on the tow which is derived from heckling, the duty is $5 only per ton, making the average duty on the heckled flax and its product tow, $10 per ton instead of $15, the duty on flax simply scutched. With these facts in view, Messrs. Hart & Co., a firm largely engaged in the flax business in New York, lately sent an agent to Canada to arrange for heckling flax in this country. We understand that on his arrival he saw Mr. Donaldson, of Toronto, and concluded to establish his works at Baden. But, coming to Stratford to purchase the scutched flax, Messrs. Marshall induced him to abandon the idea of going to Baden, and to do his heckling here. Messrs. Marshall engaged to give him sufficient accommodation immediately at their mill in Stratford, and enough flax to keep his men at work until he has had time to visit other mills and make larger purchases. The agent is prepared to purchase all the scutched flax he can obtain in Canada, and will pay for it the highest New York prices. He hopes to be able to obtain sufficient to give constant employment to twenty-five or thirty men. He has his heckles already here, and is busily occupied with the necessary arrangements to set the men at once to work. We attach considerable importance to this movement. Not only will it tend to benefit the Town of Stratford in a direct manner, but it will stimulate a growing agricultural industry throughout the country.—*Stratford Beacon.*

☞ The *Practical Farmer* gives a report of the potato crop this year, in the vicinity of Philadelphia. The Early Goodrich did not sustain its former reputation, although this is believed to have been largely owing to the season. It did not do as well on light as on heavy soil. The Michigan White Sprout did well, as did the Jersey Monitors. The Harrison did finely, and seems to be the best late potato. The Pink-eye Rusty Coats did exceedingly well. The Early Rose is almost unanimously endorsed.

Esparto Grass.—A large quantity of this vegetable for Messrs. John Taylor & Bro., and intended to be used by them for the manufacture of paper, arrived in this city by different vessels during the past few days. Esparto grass is quite plentiful in Lower Canada, but has never been of much commercial importance until its advantages as a substitute for rags were discovered.

The Gamgee Meat Preserving Process.—Professor Gamgee has been spending the summer at the West, preparing to put up beef, mutton and other meats for Eastern and European markets. He recently returned with a fine lot of beef, mutton, prairie chickens, etc., which was exhibited for a week or more before being packed and sent to England. The beef was in quarters, the mutton in carcasses. We partook of some of the steaks and found them most delicious, and are confirmed in our good opinion heretofore expressed, and in our best wishes for the success of the process, in the hands of the Gamgee Meat Preserving Company.—*American Agriculturist.*

The Wheat Crop of California.—One hundred and fourteen cargoes of wheat were shipped from San Francisco to England since July 1st last year, footing up three million centals, or five millions of bushels, valued at $6,500,000. The progress of agricultural development and enterprise in California is unprecedented in the world's history. It is but a few years since California had to be supplied with wheat and flour from Chili and the United States; now the wheat crop of California last year did much to save England from famine, and the United States from famine prices. The climate of California is very favorable, not only to the growth but to the harvesting of the wheat crop, as the plant matures when the season is so dry that neither rust nor after sprouting can take place, and the wheat may be threshed in the field and left in bags for weeks without shelter. The question now is, how long will the wheat-growing pabulum last in the soil by cropping without manuring? Much longer, perhaps, in that volcanic soil, where the inorganic (mineral) elements of plant food are in great force, than it will on our alluvial prairie lands at the west, which have already begun to fail under continuous cropping with wheat.—*Cor. American Farmer.*

Stock Department.

"Bolivar," the Favorite Short-Horn of the Year in Great Britain.

It will doubtless be interesting and instructive to Canadian farmers and stock-breeders to compare our own prize animals occasionally with successful candidates for honours in the show yards of Great Britain. We have, therefore, much pleasure in presenting our readers with the accompanying portrait of "Bolivar," which the *Farmer* (Scottish) says "may be justly considered the crack short-horn bull of this season." For our illustration and the following brief account we are indebted to the same excellent journal:

Bolivar, the favourite yearling bull, was bred by Mr. Joseph Meadows, Thornville, Wexford, and his first appearance in public was made at the last Spring Show of the Royal Dublin Society, which was held this year during the second week after Easter. He was at that time just a year old, but possessed great substance for his age. On that occasion he won the first prize in the yearling bull class, in which there were no less than 108 animals of the same age entered, many of them being of a very good description. The Towneley, or *Irish Farmers' Gazette* Plate, value £105, was also awarded at that time to Bolivar, as the best of all the prize animals of any age, sex, or breed in the cattle sections exhibited at the show.

"BOLIVAR," the Property of Joseph Meadows, Thornville, Wexford, England.

His next appearance was at the Leicester Show of the Royal Agricultural Society of England, held last July. At Leicester, Bolivar sustained his early honours, having been put first in the yearling bull class, which numbered twenty-three entries, being a very superior class, and the propriety of the award was universally allowed, not a few going even the length of saying he was the best animal in the yard.

Bolivar was not exhibited at the Yorkshire meeting, but Mr. Brierly, Rhodes House, Lancashire, who had purchased him soon after the Leicester show for 300 guineas, brought him out at the show of the Keighley Society, August 21, where, amongst other first-class bulls, he had to compete against Mr. Jonathan Peel's Knight of Knowlmere, a bull which is nearly five years old, and which had been second in the aged class at Leicester, to Mr. Booth's Commander-in-Chief, beating Commander-in-Chief, however, when shown subsequently at the Wetherby meeting of the Yorkshire Society.

At the show of the Halifax and Calder Vale Society, which was held at Halifax on the 29th Sept., Bolivar was not only first in the yearling class, but carried off also the Vice President's Cup as the best male short-horn exhibited.

The last appearance of Bolivar was at the show of the Manchester and Liverpool Society, held at Southport on the 1st October. At Southport he had to contend, amongst others in the yearling class, with Mr. Lynn's Grand Sultan, a son of Prizeman (24,870); Lady Pigot's Rosolio, the second prize yearling bull at Leicester; Mr. Dickinson's Buxton, by 10th Grand Duke, from a Lord Oxford dam; and Mr. Peel's Baron Beust, by Knight of Knowlmere, from a dam by Prince Leopold—all formidable rivals. Bolivar, however, again got the first place.

Bolivar's points are a capital style of head, a long symmetrical frame, exquisite quality of flesh, and a rare coat of rich, mossy hair. During the early part of the year, and until after the Leicester show, the roan colour of his coat had a peculiar dingy appearance, but that has now given place to a new one of the richest blooming roan hue. He is chiefly of Booth and Mason blood.

Weaning Colts.

To the Editor of THE CANADA FARMER:

SIR,—As I have had some experience in weaning colts, allow me to tell your correspondent "Gosford" what I have found to be a "good way." Put the colt and its mother in a stable; tie both side by side to a manger, in a wide stall; have nothing between them; give them an adequate supply of nutritious aliment for a few days, and the thing is accomplished. I prefer this way, because it prevents *fretting*, on the part of the mare and colt both, and, as the Irishman expresses it, about two pigs in the same pen, the one *encourages* the other to eat; so that the colt is not reduced in condition, as is too often the case during the weaning process. This mode of treatment helps to *halter-break* the colt, too, if it has not previously been done.

Another plan I have sometimes adopted, when I did not want to stable the colt—that is, started the old folks away on a visiting tour for a week or so with the mare, leaving the colt in the pasture-field with other colts; thus the two are out of hearing distance of each other, until the young one forgets its baby notions. J. B. A.

Newburgh, Nov. 9th, 1868.

The above directions are in accordance with those given in the following extract from the *Rural World*:

"When a colt is about four months old, if he has had proper care and training, and if the dam is to be used in harness, or if she is breeding again, he is old enough to be weaned. Supposing, as most farmers are obliged to do, that the mare has had to work more or less since dropping her foal, and that the colt has been allowed to follow the dam when at work—the attachment between the two has become very strong. If separated entirely and at once, and if the mare is nervous and high-strung, she will, perhaps, refuse to work, act frantic, kick, and do everything else she ought not and would not do but for the separation. On the other hand, put the colt into ever so good a pasture, feed him on grain, and do everything you may, he will run up and down by the fence, perhaps try to scale it, etc., to get to the dam, until he has run off every bit of flesh on his bones. Now, what's to be done?

"We would place the mare in a stall wide enough for her and the colt; then we would halter the colt and tie him so that he could get to the manger but not reach to the teat. It may be necessary, also, to change somewhat the halter of the dam, so that she cannot turn sufficiently to allow the colt to suck. Water the colt freely, but the dam as little as possible, for a few days, at least. If possible, feed the colt a double-handful of oats twice per day for two or three weeks before you attempt the weaning. Increase the quantity of oats a little at weaning time, even if you withdraw the extra ration by-and-by. Standing by the side of his dam he will be more quiet, and, after a little, forget his teat. The mare, also, will leave him more readily in the stable while she labours, especially when she finds him on her return. To facilitate the drying up of the milk in the mare take a little soft soap and smooth it over the udder. It may be necessary to draw out some milk first for a few times, to ease her distress. After a few days, especially if the mare is again breeding, milk will not flow very readily and be diverted naturally to the embryo foal; and, although the mare may call her colt, she will refuse to let him suck. If possible, the colt should have the best of pasture, and the company of other colts of his own age, and the daily allowance of oats, or a handful or two of meal mixed with wheat bran should be given every day.

"The latter years of our life on the farm, we never allowed the colts to follow in the field, but kept them in a loose box in an underground stable during the day. When the mares came home and were watered at night, the colts were allowed a play spell, and also at noon while the dams were feeding. The colts kept in better flesh, and gave a great deal less trouble, at weaning."

"Old Jerry."

To the Editor of THE CANADA FARMER:

SIR,—I noticed an article in the last number of the CANADA FARMER, headed "The Oldest Horse." I would just say, I can probably give as correct a history of "Old Jerry" as any of your subscribers. His colour is dark brown, except one white foot and a few white hairs in the forehead. He stands fifteen feet one inch high; girth about six feet three; head small; eye full and sharp; neck well arched; shoulder and arm powerful; deep chest; short, strong, hairy legs; knees inclining, or knock-kneed; ribs well arched; hips smooth; hind-quarters rather narrow; hind legs slightly bent; mane and tail not very heavy. He was quite timid and nervous upon being approached by a stranger, was not a fast traveller, but could make a big day at either light or heavy work. He always showed plenty of ambition, and made a good appearance. His constitution was hardy. Old Jerry was brought from near Toronto by Paddy Smith (a carter) to Aurora (then Machell's Corners), to work at the macadamizing of Yonge street. During the construction of that road, about the year 1845, Jerry was purchased by Samuel Machell, Esq., now of King Station, from Paddy, for a small sum; and about four years after Machell sold him to Moses Yoder, who was then residing in the Township of King, to work on his farm. Mr. Yoder, shortly after the purchase, removed to Elgin County, not forgetting to take Old Jerry along. The age of Jerry now is about thirty-one years.

A HORSE OBSERVER.

Another Old Horse.

To the Editor of THE CANADA FARMER:

SIR,—Having seen an account in the last number of the CANADA FARMER about the oldest horse in the new Dominion, I thought I would write and let you know that there is one as old, if not older, which can be seen on lot No. 18, second concession of the Township of Plympton, County of Lambton. This horse, *Old Charley*, was foaled in the year 1837, or the year of the Rebellion, which will make him thirty-two years of age next spring. This horse has been subjected to the most severe toil. In his younger days he ran many a race in the Township of London, and few could beat him on a mile heat. He was afterwards used as a team horse until he was seventeen years of age; since that time he has worked on a farm. It is only three years since he travelled forty miles in half a day, and last spring he travelled twenty-five miles in three hours and a half. When Old Charley is let loose in a field with other horses, he will play like a colt. He is young in appearance, can hold his own with most young horses, and is sound with the exception of a slight touch of the heaves. D. M. ROBERTSON.

Wyoming, November 5th, 1868.

☞ Hon. John Carling recently shipped from London to Cornwall, for the Hon. John Sandfield McDonald, a fine ram which took the first prize at the Michigan State fair, and two Suffolk pigs, first premium of the Western Fair.

VETERAN HORSES.—A correspondent of the *Western Rural* says: I have two bright bay horses—a mare and a gelding—which I have owned and worked on a farm and on the road since they were four and five years old respectively. The mare is thirty years old, and the horse thirty-one this spring. I have ploughed two acres per day, two and three days in succession this spring in ten hours; I have ploughed sixteen acres in five days with them when they were young.

SHEEP AT U. S. FAIRS.—The Oshawa *Vindicator* says of the Missouri State fair:—The sheep were very largely represented from Kentucky, Indiana, Illinois, Missouri, and Canada. Mr. Millar was there and won honours with his splendid stock of Cotswolds, Leicesters and Shropshire Downs, but Mr. Toms, as usual, led in his department. In long wool sheep, including Leicesters and Cotswolds, and their crosses, he took first on aged ram, first on yearling ram; this is all he showed in this class. On Southdowns, first on aged ram, first on yearling do., first on aged ewes, first yearling ewes. Sweepstakes—best ram and three ewes, first prize; best ram and ewes, first prize; best three ewes, fat, first; best ewe, fat, first; best fat ewe, two years old, first. Sweepstakes on the best flock of sheep, the Society's grand prize of $50 and the blue ribbon. At the Indiana State fair, on Southdowns, he received all the first and second prizes; first on Leicester ram. On pigs at St. Louis, first on boar, first on sow.

Window Propagating Tank.

The following description and illustration of an ingenious contrivance for propagating slips and forcing seeds by a simple and economical application of bottom heat, is taken from the *American Journal of Horticulture*.

"Its chief recommendations are cheapness, utility, and the slight cost both of labour and material with which it can be run.

The chimney of an ordinary kerosene lamp is made of tin, double, and water-tight, so as to hold water. The water in this chimney is connected with the water in the tank by means of pipes through which the water flows. One of the pipes is connected to the chimney at the top, and the other at the bottom, the pipes entering the tank in the different divisions, as shown in fig. 2. By means of this arrangement,

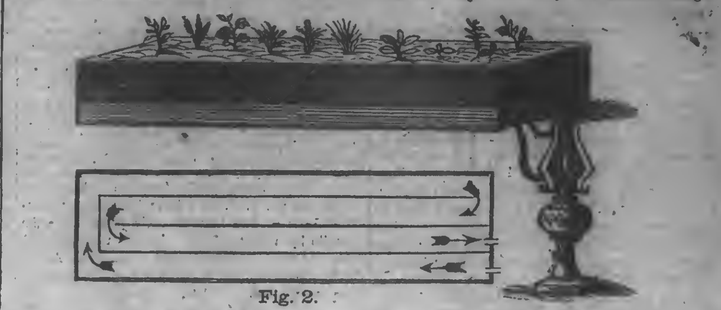

Fig. 2.

when in operation, the water in the tank is kept in constant circulation, according to well-known principles, warming the bed of earth placed over the water, giving to cuttings and seeds, placed in the bed of earth, what is known as bottom heat. Cuttings of roses, shrubs, grapes, and, in fact, of almost any of the trees or plants found in door-yards or lawns, may be started into growth with it.

The cost of constructing one for an ordinary sized window will not exceed five dollars, and may be used many seasons."

Horticulture in Quebec.

To the Editor of THE CANADA FARMER:

SIR,—I have been so busy that I have not had time to write, as I intended, an account of the Flower Show of the city of Quebec. I am afraid it is a great many days after the fair to give any interest to an account of the show of the Quebec Horticultural Society. The great strength of the Society is in the subscriptions of resident gentry, which give the Society a narrow basis. It is not the fault of these gentlemen that the Society is apparently exclusive, for there is no bar to any one paying two dollars to become a member. But they *don't*. It is not taken up so generally by amateurs and non-professionals as it should be. The consequence of this is, that a great deal of the show consists in the display of such things as a gentleman's establishment can send to exhibitions; green-house plants, oranges, lemons, peaches, plums of choice sorts, and grapes, show in force. The grapes of J. Le Moine, Esq., Spencer Grange, were most excellent, as were many others. The black Hamburgh, [illegible] and the delicious Sweetwater [illegible] The above-named [illegible] that size. There is an old lady in the suburbs of Quebec who makes the growth of grapes in the open air her hobby. And admirably she succeeds. In her yard you may see vines (stock [illegible]) growing in flour barrels cut in two. They [illegible] of this letter, as many as forty bunches of grapes on them, most of which will ripen. When the snow comes she will put them in a cellar till the spring. Mrs. Farquhar (for this is our friend's name) has done, in my opinion, a great good in showing that grapes can be grown in our severe climate in *the open air; and* I should like to see a prize offered by this Society for such results as these, because, in such a hard country as this, *anything* that will tend to make life more enjoyable is not only a thing to be simply desired, but earnestly sought after. We are too apt to give the go-by to any idea that our acres of ground can be rendered more productive.

The show of vegetables was very good, comprising first-rate potatoes, good carrots, parsnips, beets, onions, &c. There was a curiosity in the way of cucumbers. Some ingenious man grew some enormous cucumbers, of such great length and irregular shape as to make them represent the name of this Province. I doubt the utility of this sort of thing.

Some beautiful honey was shown by Mr. Joseph Paxton.

There are some prizes for amateurs, but amateurs do not yet take sufficient interest in these things. Perhaps they will by-and-by.

The season has been stretched out to a favourable length. Winter has not yet set in, though it is now snowing.

Potatoes cheap; hay dear; cattle cheap.

PHIALA.

NOTE BY ED. C. F.—Some inquiries appended to the above communication will be noticed in our next. A plant specimen referred to did not arrive

Saving Trees Girdled by Mice.

AT the February meeting of the Northern Ill. Horticultural Society, D. B. Weir, of Lacon, read a paper "On Saving Girdled Fruit Trees." He said he had over a hundred trees, seven years planted, completely girdled by mice. There had been for some time a heavy snow on the ground; and mice being plenty and in a starving condition, with nothing else to eat, they ate all the bark from the trees so far as they could reach; some of them for a foot up and down all around; and portions of the sap wood in some places half an inch deep. As soon as the damage was discovered, which was on the first thawing days, he banked the snow around the trees, and as soon as the soil thawed he banked that a foot high about the tranks.

This was all the attention they received; and today they have all the damaged parts covered by almost as thick a coating of bark as the uninjured portion of the trees. When the girdling is done high up on the trees, banking with soil will be impracticable. If the wounded parts are too high to reach by banking, clay may be bound on with a bandage. The sooner the surface is protected after injury the better. The death of the tree is caused by the seasoning of the sap-wood

Entomology.

The Wheat Midge.

The ravages of this pernicious insect appear to have been less wide-spread this year than usual, though we have observed and heard of its presence in various quarters. Now that the farmers have for the most part threshed their wheat, they can tell to what extent the grain has been affected by this insect, and we trust that they will employ some of the long winter evenings in writing out their experience and acquainting their brother farmers with it through our columns. Those who have been troubled with the midge we strongly advise to plough under their wheat stubble as deeply as possible, and burn all the chaff and refuse left from the threshing; they will thus destroy a large proportion of the larvæ of the insect, and prevent, to some extent, its re-appearance next year. "An ounce of prevention is worth a pound of cure." If farmers will not make some little effort—take some little trouble to prevent the recurrence of a particular insect foe—they cannot expect to receive much pity when they come to bemoan their wasted crops next year.

So much as regards *prevention;* but is there any *cure?* It is very hard to say. We believe that there is a cure, but it is not easy to apply it, and if there should be expense attending it, some will at once cry out that "the remedy is worse than the disease—we will have none of it." Some months ago (C. F. May 1, page 134), we spoke of the parasites of the wheat midge, and the possibility of introducing them into this country; we also mentioned that we were in correspondence with an English Entomologist on the subject. Mr. Francis Walker, F. L. S., of the British Museum (Entomological Department), London, England—a well-known authority on *Diptera*, the order to which the midge belongs, as well as on other insects—wrote to us on the subject some time ago. We did not publish his remarks before, as we hoped to receive some further information; but now all attempts will have to be deferred to another season. He stated as follows: "I doubt much whether the parasites of the wheat midge can be introduced successfully into Canada. I can hardly attend to that matter this year, and I know only three Entomologists who are acquainted with the tribes of insects to which the parasites belong, and I have written to them about the matter. In many cases I think that insects are more kept in check by other means than by their parasites. *Platygaster tipulæ* is the chief parasite of the wheat midge; the British species of *Platygaster* are very numerous; there are probably several species in Canada, and perhaps one of them may become a parasite of the wheat midge. I hope that some Canadian Entomologist will study there the species of that genus, and of other parasitic Hymenoptera, and their economy. Besides the wheat midge, there may be in Canada some species of *Cecidomyia* feeding on grapes, and each attacked by a species of *Platygaster;* the latter, when it assumes the fly-state, might be placed close to the wheat midge, and perhaps in time it will take to it as its prey."

There are a large number of species of *Cecidomyia* known to inhabit North America, and two are mentioned by Baron Osten Sacken, in his monograph on this family, as feeding upon the wild grape. The habits of these, however, are different from those of the wheat midge, the former producing a gall, and the latter not. Another midge attacks the gooseberry, causing the fruit to become prematurely red and rapidly putrid. It is a well-known insect, and may be found to have parasites which could be utilized as Mr. Walker suggests. The experiment is worth trying; but our own impression is that it is very unlikely that the parasite of one midge would take to another, except where it was shut out from its own proper species, and then where both are exposed to its attacks, it would prefer the species natural to it rather than the other. The great difficulty in the way of effecting these experiments successfully, and of introducing a midge-parasite from one country to another, is the extreme minuteness of the objects, which demand an amount of time and patience for observation that few of us can afford to give them.

Entomological Quackery.

We clip the following paragraph from the *Iowa Homestead* of July 22, 1868:

The Curculio.—A correspondent of the *Canada Farmer*, writing from Sarnia, says that he saved his plums from the curculio in the following manner: He put woollen rags around the base of the trunks of his trees, having first steeped them in tanner's oil, renewing the application of oil after every heavy shower. He put chloride of lime in a saucer in the fork of the tree. He spread white cloths on the ground under the trees, poured sulphuric acid on the lime, and the fumes brought down all insects from the trees. He also tried jarring the trees, and by these means he succeeded in raising a large crop of plums.

This reminds us of a letter to a noted quack which we once came across, and which read as follows: "Dr. Curcali—Dear Sir: I had a pain in my stomach yesterday; so first of all I took a dose of your never-failing electric oil; then I tried a dose of Dr. Humbug's infallible elixir of lime; and lastly I swallowed a dose of cold-drawn castor oil. In three hours' time my stomach was all right again. Please let me know whether it was the electric oil, or the elixir of lime, or the castor oil that cured me. Yours, truly, Samuel Simpleton."

We incline to believe that it was the "jarring the trees" that saved the plums; and that the "tanner's oil" and the "chloride of lime" might just as well have been daubed on to the roof of the house, for any effect that they had towards keeping off the curculio. Will people never find out that curculios can fly, and that attempting to head them off from crawling up the trunks of plum trees by oily bandages is all a matter of moonshine?—*American Entomologist.*

Note by Ed. C. F.—We have invariably recommended our readers to save their plums from the curculio by means of the "jarring process," and gathering up and destroying all fallen fruit. Any of the other methods that so frequently go the rounds of the press we believe to be utterly worthless

An Insect Powder.

A well-known German traveller, F. Jager, in his "Sketches of Travel in Singapore, Malacca, Java," (Berlin, 1866), describes the powder of the *Pyrethrum roseum* as a specific against all noxious insects, including the troublesome mosquitoes and those which attack collections. He says:—"A tincture prepared by macerating one part of the *Pyrethrum roseum* in four parts of dilute alcohol, and, when diluted with ten times its bulk of water, applied to any part of the body, gives perfect security against all vermin. I often passed the night in my boat on the ill-reputed rivers of Siam without any other cover, even without the netting, and experienced not the slightest inconvenience. The 'buzzing,' at other times so great a disturber of sleep, becomes a harmless tune, and, in the feeling of security, a real cradle song. In the chase, moistening the beard and hands, protects the hunter against flies for at least twelve hours, even in spite of the largely increased transpiration due to the climate. Especially interesting is its action on that plague of all tropical countries, the countless ants. Before the windows and surrounding the whole house where I lived at Albay, on Luzon, was fastened a board six inches in width, on which long caravans of ants were constantly moving in all directions, making it almost appear an uniformly black surface. A track of the powder, several inches in width, strewed across the board, or some tincture sprinkled over it, proved an unsurmountable barrier to these processions. The first who halted before it were pushed on by the crowds behind them; but, immediately on passing over, showed symptoms of narcosis, and died in a minute or two, and within a short time the rest left the house altogether."

The Plague of Insects.—The Insect Exhibition held in Paris has led to the formation of an Agricultural Entomological Society. The objects of this Society are the propagation of useful insects and the destruction of noxious ones.

Poultry Yard.

Ontario Poultry Association.

A meeting of this Association was held in the Agricultural Hall, on Monday, 9th inst., but, owing to the unfavorable weather, there was not a large attendance. After the usual preliminary routine business, the Secretary read a communication from Mr. R. S. M. Bouchette, Commissioner of Customs, in reference to imported poultry, which was published in our last issue, and from which it appears that these importations are not exempt from duty, as some of the members had been led to believe. The subject of the proposed Fall Show was then discussed, but taking all things into consideration, it was not deemed advisable to hold one at this late season of the year, and the project was therefore abandoned. This will, no doubt, be a disappointment to many intending exhibitors, some of whom have imported birds from Europe at considerable expense. The Society have, however, encouraging prospects for a good exhibition next year, and several communications were read which show that through their means considerable interest has been excited throughout the country in improved breeds of poultry, and a number of reports were furnished of the success achieved at various agricultural exhibitions by birds procured at the last poultry show in Toronto. Col. Hassard's Cochin Chinas, in particular, had won distinction wherever they had been exhibited; and one breeder had raised from a pen of his birds forty chickens during the past season. The Brahma Pootras furnished by Mr. T. McLean had also given entire satisfaction; and in other breeds a marked improvement in the poultry yard was manifest wherever the Society's stock had been introduced. Some important measures were discussed with a view to putting the Association on a still better footing, and a committee was appointed to consider them more fully, and report, if possible, at the next meeting in December.

Brahma Pootra Fowls.

To the Editor of The Canada Farmer:

Sir,—On seeing the cuts of the dark Brahmas in the Canada Farmer (vol. 5, No. 1), that were imported by Mrs. Varley, of Toronto, and always having a fancy for fowls, the splendid representation rather gave me the hen fever. I consequently attended the Ontario Poultry Show held in Toronto last April, for the express purpose of purchasing; but was rather surprised to find that the birds were held so high, the first prize pair of dark Brahmas imported being valued at fifty-five dollars, and the second prize pair, imported, forty dollars. However, I purchased the second prize pair, imported by R. A. Wood, Esq., Toronto; also a cock and two hens of the light Brahmas from him; but the dark hen proved barren. Consequently, I again visited Mr. Wood's poultry yard in order to purchase another, as he told me when I purchased the first lot that he expected more out soon; and I found that another pair had arrived, and also that he had purchased the first prize pair imported by Mrs. Varley, as above referred to, and that he had a fine lot of chickens raised from them, all of which I purchased (with the exception of one of the cocks, that died July last); and now, having Mr. Wood's entire stock, in addition to my own, it makes me a yard of over fifty birds, second to none in the Province. There are a number of pairs of imported fowls among them, including birds that took the first and second prizes at the last Ontario Poultry Show, and I shall spare no pains nor expense in breeding and keeping them pure, and shall supply customers with fowls and eggs at prices that cannot fail to give satisfaction. For list of prices see advertisement in this number.

Brooklin, November 8th, 1868.

The Household.

A Lady's Letter.

To the Editor of the Canada Farmer:

Sir,—In your last issue (October 15th) I find an interesting letter from "Cultivateur," on the subject of "The Ladies and the Canada Farmer." My bump of feminine esteem is gratified by "Cultivateur's" assertion that the reticence on our part, of which he speaks, is to be regretted. I had never thought of the possibility of such a case, but now that the subject is placed before us in that gentleman's candid and pleasant style, I am quite willing to confess that I think a little stirring up might do us good.

For my own part, I have been an interested reader of your valuable journal since its first publication, and like it better this year than ever. In our household it is eagerly looked for, and thoroughly read and studied. I believe it is the same in many, many homes, and that *my* sex are as anxious for the arrival of the Canada Farmer as your own. If this be so, lack of interest cannot be laid to our charge. Neither do I think that, as a rule, we are unwilling to impart ordinary information which we may have found valuable to ourselves; but I *do* think the Canadian women, educated ones too, have a habit of thinking and saying, "Oh, *everyone* knows *that*," and thus information that might be of real value to others is often lost. I am myself guilty in this sense, since I should never have dreamt of writing for so substantial a periodical as the Canada Farmer but for "Cultivateur's" reminder. But now, please, since you say we ought to write, you might give us a hint also as to the subjects for our feminine pens. Am I to enter on the poetical, and talk of our really beautiful Canadian flora, and of the glorious tints of foliage displayed on every side this autumn?—or must I keep to the practical, and tell you of the consternation of our new neighbours on hearing my father's plan of soiling cattle, and which in their opinion will assuredly lead us to ruin by a short track? Perhaps you may enjoy, as I did, hearing of the conclusion arrived at by some labourers here—that the boiled hoofs dug in under our young orchard were for the express purpose of *raising calves* by a new English method.

If the doings on our "farm of ten acres," or the comments thereon of an unusually ignorant neighbourhood, would be of interest to you, Mr. Editor, to "Cultivateur," or to any of your readers, gladly would I endeavour to vie even with my American cousins, and try to lift my grain from the mountain of opprobrium resting on our *silent sex*, and thus prove that we are willing and ready to do our share when once shown that our efforts are appreciated or required.

Thanking you, Mr. Editor, warmly for the pleasure and profit so constantly afforded us in your valuable paper, and thanking "Cultivateur" too for his kindly remarks, I am sincerely yours.

A YORKSHIRE LASS.

Hull Township, Oct. 25th, 1868.

Note by Ed. C. F.—"Cultivateur" has also our thanks for having elicited the above pleasant communication, which is proof direct of the truth of his assertion, that there is literary aptitude among the female readers of the Canada Farmer to enrich its pages, if it could only be called forth. We hope that our fair correspondent will follow up this first letter by others in her own style, and we prefer leaving the choice of subject to herself. Anything in the range of domestic economy or rural affairs will be in place. We trust also that others of the same sex, stimulated by this example, will favour us with their communications.

The Chemistry of Furniture.

Young housekeepers do not always understand the theory of the chemical and mechanical action of different substances on articles of furniture. The substances from which furniture is chiefly exposed to injury are water, oils, alcohols and acids.

Acids act on marble. Marble is itself composed of carbonate of lime; that is, it is a compound of carbonic acid and lime. Now the carbonic acid has a comparatively weak affinity for lime, and most other acids will prevail over it and take its place when brought into contact with it; thus destroying the texture of the stone, liberating the carbonic acid, and leaving nitrate of lime, or sulphate or acetate of lime—as the case may be—in the form of a white powder in its place. But oils, alcohols and water produce no effect whatever on marble.

All varnished or polished surfaces of wood, on the other hand, while not injured usually by acids, are attacked by alcohol. Varnishes are composed of different gums and resins, which are generally soluble in alcohol. Many of them are made by dissolving the material in alcohol, so as to liquefy them, and then when they are applied the alcohol evaporates, leaving the gum or resin in a thin, even coating over the whole surface.

If any alcoholic substance comes upon such a surface, whether it be alcohol itself as used for lamps, or spirits of any kind, or even wine, which contains but a small percentage of alcohol, the varnish is attacked, a portion of it dissolved, and the brilliancy of the surface is destroyed.

Oil will not attack either marble or varnished surfaces, and will not do any injury except to naked wood or other porous substances which admit it into the pores, from which it cannot afterwards easily be expelled.

Water affects no substances except such as have open pores exposed, in which case it enters and causes the substance to swell, or such as are soluble in water, as glue in joints, and mucilage or gum-arabic, used sometimes for attaching superficial ornaments to fancy work.

The practical lesson to be learned from this is, that housekeepers must take care in dealing with furniture to keep water away from everything soluble in water, oil from everything porous, alcohol from varnish, and acids from marble.—*Rural American.*

Poetry.

Our Fathers.

BY HON. JOSEPH HOWE.*

Room for the dead! Your living hands may pile
Treasures of art the stately tents within;
Beauty may grace them with her richest smile,
And genius here spontaneous plaudits win.
But yet, amidst the tumult and the din
Of gathering thousands, let me audience crave;
Place claim I for the dead. 'Twere mortal sin,
When banners o'er our country's treasures wave,
Unmark'd to leave the wealth safe garner'd in the grave.

The fields may furnish forth their lowing kine,
The forest spoils in rich abundance lie,
The mellow fruitage of the clustered vine
Mingle with flowers of every varied dye;
Swart artizans their rival skill may try,
And while the rhetorician wins the ear,
The pencil's graceful shadows charm the eye;
But yet, do not withhold the grateful tear
For those and for their works who are not here.

Not here? Oh, yes! our hearts their presence feel,—
Viewless, not voiceless; from the deepest shells
On memory's shore, harmonious echoes steal;
And names which in the days gone by were spells,
Are blent with that soft music. If there dwells
The spirit here our country's fame to spread,
While every heart with joy and triumph swells,
And earth reverberates to our measured tread,
Banner and wreath should own our reverence for the dead.

Look up, their walls enclose us. Look around;
Who won the verdant meadows from the sea?
Whose sturdy hands the noble highways wound
Through forests dense, o'er mountain, moor, and lea?
Who spanned the streams? Tell me whose works they be,—
The busy marts where commerce ebbs and flows?
Who quelled the savage? And who spared the tree
That pleasant shelter o'er the pathway throws?
Who made the land they loved to blossom as the rose?

Who in frail barks the ocean surge defied,
And trained the race that live upon the wave?
What shore so distant where they have not died?
In every sea they've found a watery grave.
Honor forever to the true and brave
Who seaward led their sons with spirits high,
Bearing the red-cross flag their fathers gave;
Long as the billows float the arching sky
They'll seaward bear it still—to venture or to die.

The Roman gathered in a stately urn
The dust he honored—while the sacred fire
Nourished by vestal hands, was made to burn
From age to age. If duly you'd aspire,
Honor the dead; and let the sounding lyre
Recount their virtues in your festal hours;
Gather their ashes—higher still, and higher
Nourish the patriot flame that history dowers;
And o'er the Old Men's graves go strew your choicest flowers.

* Written on the occasion of holding the first Provincial Industrial Exhibition in Nova Scotia.

Miscellaneous.

Alcohol.

The following extract is part of an article in the *Scientific American* on alcohol, regarded in a purely scientific point of view. We commend the facts stated to the thoughtful consideration of all concerned:—

"We judge of the nature of alcohol by its effects on animate and inanimate bodies. Take the latter first. Alcohol is one of the best, if not the very best antiseptic known. Matter, which could be by no other means so well preserved from decay, change of form, or alteration of structure, is held *in statu quo* by alcohol. Extracts of the qualities of herbs, minerals and animal substances, useful in medicine and the arts, can be preserved in their purity and power by no other agent so well. Beside its antiseptic qualities, alcohol is a stimulant, aiding in the effect of the drugs or extracts with which it is combined. It stimulates the physical forces of the human system when rendered inactive by disease; it is a 'force-put,' a 'make-shift,' as mechanics would say; useful to keep the enfeebled body from the grave, and to impart new life to organs almost past sensation by other means.

And there its usefulness ends. It never imparted additional strength to the robust; it never made the old young; it gives nothing; it only acts on what there *is*. When pure, it is a deadly poison, antagonistic to life. Its effect on the lining of the stomach, intestines, and other internal organs—the mucous membrane—can be produced even upon the epidermis, or external skin, to such an extent as to blister. Alcohol does not assimilate—has no affiliation with the secretions of the human organism. It passes out of the stomach in precisely the same condition in which it entered it. It shows itself in the breath of the habitual drinker, in his perspiration, his evacuations. It is still alcohol. Part may be retained in the blood, which it thins and weakens. For a time it is held in the brain, stimulating it to unnatural activity; but it leaves the organ as it was before, or rather enfeebled by the task it performed while under the subtle influence of the wine spirit.

☞ It is stated that rags, as a material for paper making, have been so far superseded by Esparto grass that seven-tenths of British paper is now made from it. The London *Times* is printed on paper made of this material.

Peat Meadows are receiving much attention in Massachusetts. Many of them have passed into the possession of manufacturing companies. The peat is pressed in a machine, dried, and used for fuel, especially for furnaces.

Singular Facts in Human Life.—The average length of a life is about 28 years. One quarter die previous to the age of 7, one-half before 17. Only 6 of every 100 reach the age of 65, and not more than 1 in 500 lives to 80 years of age. Of the whole population on the globe, it is estimated that 90,000 die every day, about 3,700 every hour, and 60 every minute, or 1 every second. These losses are more than counterbalanced by the number of births. The married are longer lived than the single. The average duration of life in all civilized countries is greater now than in any anterior period. Macauley, the distinguished historian, states that in the year 1685—not an unhealthy year—the deaths in England were as 1 in 20; but in 1850, 1 in 40. Dupin, a well-known French writer, states that the average duration of life in France, from 1776 to 1846, increased 52 days annually. The rate of mortality in 1781 was 1 in 29; but in 1850, 1 in 40. The rich live on an average 42 years, the poor only 30 years.

Among the Calves.—Jim Smith was a noted auctioneer. One day he was selling farm stock. Among the articles to be sold was a heifer, very attractive in her appearance, and consequently "Jim" dwelt quite extensively on her many excellencies, winding up with the eloquent flourish that she was as "gentle as a dove." Thereupon a long, slab-sided countryman, whose legs were some twelve inches longer than his pants, approaching the heifer and stooping down, commenced handling her teat. Bossy, not relishing such familiarity, lifted her hoofs and laid "Greeny" sprawling some ten feet off.

"There," said "Jim," "that shows one of her best traits; she'll never allow a strange calf to come near her!"

"Greeny" meanwhile picked himself up, and giving his bushy pate a harrowing scratch, exclaimed: "No wonder, when her own calf has been bleating around her all day!"

Markets.

Toronto Markets.

CANADA "FARMER" Office, Nov. 14th, 1868.

THE PRODUCE MARKET.

The grain market has been quiet and dull. Spring wheat has kept steady, but in other grades there has been a gradual decline. Flour has also declined. Provisions are without material change.

FLOUR AND MEAL.

Flour—The market has been dull and drooping. Lots of No. 1 superfine were offering early in the week at $5 5c., and later at $5; declining to-day to $4 80c., at which price a 100 bbl. lot changed hands. The demand is very limited, and latterly it has been difficult to effect sales. Extra is nominally worth $5 75c. A lot was offered at that price without buyers.

Oatmeal—There is a small trade doing. 100 bbl. lots sell at $8. Broken lots are worth $6 25c. to $6 50c.

Cornmeal—Worth, in 100 bbl. lots, $4. In smaller lots, $4 25c. to $4 50c.

GRAIN.

Wheat—The market is very quiet. There is some demand for spring wheat, and not much offering. The last sales of car lots were at $1 11c. To-day a car of midge-proof sold at $1 10c., f.o.b. Fall wheat was offering at from $1 10c., to $1 20c., with no buyers. There is little or no demand for fall, and lots are almost unsaleable. On the street market there is little or nothing doing. The roads are in such a bad condition and the markets so dull that farmers have no inducements to bring their grain in. Fall wheat sold as low as $1 10c. on the street to-day, and spring wheat on the street sold at $1 8c.

Oats—The market is quiet and dull. Sales of lots were made at 50c., on the track—on the street market 53c., is paid.

Barley—The market is quiet and dull. There is now little or nothing doing. Two cars No. 2 sold at $1 26½c. Holders are generally asking $1 35c., and buyers would pay $1 30c., for choice lots. On the street market there is only a very limited quantity coming in. Buyers are paying from $1 30c. to $1 35c.

Peas—Market very dull. We heard of no sales. Street price 85c. to 86c.

Rye—Market quiet. Selling on the street market at 85c.

PROVISIONS.

Pork—There is as yet very little new mess in the market. No enquiry. Prices are still nominal.

Cheese—There is no change in the market. The factories still hold out for higher prices than buyers are inclined to give. Prices are unaltered at 11c. to 11½c., for factory.

Bacon—In better supply. Prices remain firm. No quotations given.

Lard—Firm, and in good demand. The present high price of butter tends to keep lard firm.

Butter—As the closing of navigation is now daily expected, lots for shipment to England are not so desirable. Still, on the whole, there is no weakness, it being generally considered that the small stock reserved will be wanted for local business. Fine butter finds a ready sale, and we hear of some ventures to New York without loss. Anything, however, below first class hangs fire at quotations. Prices in the country have kept advancing while we have remained stationery, and a margin for dealers has become very fine indeed. Should the demand in England slacken, we have no other chance than to decline prices here, it being quite apparent now that New York can be supplied from the west with its local requirements, and the Californis drain on New York being light, there is no prospect of stiffer rates in that city—unless for extra choice. Ordinary, 20c. to 21c.; medium, 22c. to 22½c.; sweet dairy (for retail grocers), 23c., to 24c.

Eggs—The high prices have checked consumption—prices nominal at 19c. to 20c.

THE CATTLE MARKET.

Trade during the week was good. There was a fair demand for cattle to export to Montreal. We quote per 100 lbs. dressed weight: 1st class, $6 to $6 50c.; 2nd do., $5; 3rd do., $4. *Sheep* are offering freely. There is an active demand. All the lots offering found buyers. We quote:—1st class, $4.; 2nd do., $3.; 3rd do., $2.

Hides and Skins—Hides, green, rough per lb., 6c., to 6½c.; do. cured and inspected, 7¾c. to 8½c.; do. dry, 11c., to 13c. Calfskins, green, 10c.; do. cured, 12c.; do. dry, 18c. to 20c. Sheepskins, 60c.

Dressed Hogs—The market is hardly fully supplied. The lots offering are principally railway lots. Prices range as follows:—Weighing 120 to 150—$6 to $6 25c.; 150 to 200—$6 25c. to $6 50c.; 200 to 300—$6 50c. to $7. Choice farmers' hogs for butchers might bring $7 25c., and even higher.

HAY AND STRAW.

Hay—During the week the supply was not equal to the demand, on account of the bad condition of the roads. Several loads brought as high as $20. Selling at from $18 to $20.

Straw—Very scarce. The loads offering are nearly all rye straw. Selling at from $10 to $14.

Apples—The demand continues good, and superior qualities are higher. From $1 to $2 per bbl. is paid.

Salt—Market firm. American unchanged, $1 60c., in bbls. on the wharf. Liverpool coarse is worth $1 50c. to $1 40c. Canadian sells at $1 60c.

Hops—Selling in single bales at from $10 to 1

Potatoes—A great many car loads on the market at 90c. Some consignators are holding at 75c., but no sales could be effected at those prices. Retail lots sell at from 75c. to 80c.

Hamilton.—*Wheat*, white, $1 25; do, red winter, $1 07 to $1 08; do, spring, $1 03 to $1 06. *Barley*, $1 25. *Peas*, 80c. to 85c. *Oats*, 45c. to 50c.

Galt.—Wheat continues at about last week's prices. *Potatoes* are scarce, and sell at from $1 to $1 12½ per bag. *Turnips* from 12½c. to 15c. per bushel. *Carrots* from 20c. to 25c. per bushel. *Oats*, 48c. to 50c. Poultry coming in more plentifully. *Turkeys*, 60c. to 75c. *Chickens*, per pair, 25c. to 30c. *Geese*, 37½c. to 50c. each. *Ducks*, 37½c. to 50c. per pair. *Pork* from $7. *Hay*, $11 to $12 per ton.

Guelph Markets.—Fall wheat, $1 20 to $1 28. Spring wheat $1 05 to $1 09. Oats, 55c. to 58c. Barley, $1 15 to $1 20. Peas, 80c. to 81c. Wool, 27c.

London Markets.—Fall wheat, white, $1 06; midge-proof, $1 to $1 05; spring wheat, $1 04 to $1 05; barley, $1 10 to $1 20; oats, 71c. to 76c.; peas, 76c. to 81c.; corn, per bushel, 85c.

THE CANADA FARMER is printed and published on the 1st and 15th of every month, by the GLOBE PRINTING COMPANY, at their Printing House, 26 and 28 King Street East, Toronto, Ontario, where all communications for the paper must be addressed.

☞ Subscription Price $1 per annum, (POSTAGE FREE,) payable in advance. Bound volumes for 1864, 1865, 1866 and 1867, may be had for $1 50 each. Subscribers may either begin with No. 1 of the present Volume, or with the first No. of any preceding volume. No subscriptions received for less than a year, and all commence with the first number for the respective years.

CLUBS will be furnished at the following rates:—

TEN COPIES for	NINE DOLLARS.
TWENTY COPIES for	SIXTEEN DOLLARS.
FORTY COPIES for	THIRTY DOLLARS.
ONE HUNDRED COPIES for	SEVENTY DOLLARS.

To Agricultural Societies ordering more than 125 copies, THE FARMER will be sent at SIXTY CENTS.

THE CANADA FARMER presents a first-class medium for agricultural advertisements. Terms of advertising, 20 cents per line space. Twelve lines' space equals one inch. No advertisement taken for less than ten lines' space.

Communications on Agricultural subjects are invited, addressed to "*The Editor of the Canada Farmer*," and all orders for the paper are to be sent to GEORGE BROWN,
Managing Director.

VOL. V. No. 23. TORONTO, CANADA, DECEMBER 1, 1868. POSTAGE FREE.

The Month.

DECEMBER brings the indubitable winter, as surely as July does the summer. Whatever dreamy expectations we may have had of possible Indian summer, vanish now. Pleasant weather indeed we may have, but it will be pleasant wintry weather, with perhaps now and then a day so fine and warm that it seems to have lost its proper place in the year. Clear, bracing, but chilly, air will quicken the pulse, and send the blood coursing through the veins with unusual vigour. The snow will wrap the earth in its white coverlet, and all things will yield to the sleep of winter, and to the reign of the frost king.

The following are the mean temperatures for December:—

Stratford	22°65′
Hamilton	26°96′
Berrie	23°94′
Toronto	25°96′
Belleville	22°85′
Montreal	24°12′
Quebec	21°20′
St. John, N. B.	25°93′
Halifax	28°00′

We are accustomed to think and speak of winter as a season of comparative rest and leisure for the farmer. But how far that is true and applicable to individual cases, depends on a variety of circumstances. Winter affords but little respite to the man who has a large area of wild land to clear, or a numerous herd of cattle to feed. These, however, are exceptional cases, and most farmers, when winter fairly sets in, feel that they are less driven than at any other period of the year. But while "broken weather," as it is often termed, lasts, every one has enough to do. That charming writer on rural affairs, "Ike Marvel," says: "Even into December the work of country improvements may go safely forward; the clearing of new land, the thinning of over-crowded forest growth, the building of walls, the construction of walks and roads,—for these, severally, or together, no better time can be found than that which immediately precedes the locking frosts of winter. And when the dead-lock is fairly established,—so far as treatment of the land goes,—the open sunny weather of December still invites us many a day out of doors. If we have rocks to move, they glide easily over a frosted and stiffened turf; the brambles and waste growth of outlying pastures cut easiest when the earth is locked unyieldingly about their stems; the woods, despoiled of their leaves, give free insight and outsight to their most sequestered nooks." These are but examples of the thousand and one things that may be done just at the setting in of winter, and there are few so beforehand with their work as not to be caught by the "dead-lock" with some needful preparations or unfinished undertakings that must needs be postponed until another year. Most people, in regard to work, are like children in respect to tempting food; too greedy. The child's eye is proverbially larger than his stomach, and even so the farmer's eye readily takes in more work than his hand can accomplish. Indeed, generally speaking, plans and achievements too often correspond very poorly. "To will is ours, but not to execute." Happy are those on whom winter does not shut down with a host of half-accomplished schemes of preparation and improvement!

The hints given last month, as to the care of stock, are just as applicable this month, and will become more so as the temperatures go down into mid-winter. In fact, the care of his animals may be put down first on the list of the farmer's winter duties. Whatever arrangement or expedient can be contrived to make this duty easier, and secure its being faithfully performed, should by no means be neglected. Convenience of access to food, well-hinged and securely fastened doors; ventilation without currents of cold air from unstopped cracks and openings; ready means of clearing out manure; are things that should by all means be secured. Manure-making is also a December as well as November job—indeed, it is a job for all the year round. The great want of every farm in the land is more manure, and no opportunity of making it should be let slip. One valuable material for manure-making can on some farms be better got at and hauled in the winter time than at any other season, namely, swamp muck. Any farmer who is fortunate enough to be within a mile or two of any ashery, would find it pay to haul as much as possible of the leached ashes on to his land, in good sleighing. It is heavy material, and far more of it can be hauled in a sleigh, when the winter roads are at their best, than on a waggon, however good the wheeling may be.

Wood-cutting and hauling is another item of winter work on the farm. The year's supply for the family should be thought of now. To burn green wood, and to bring it load by load from the bush as required, are among some of the most disgraceful points of slipshod farming. The wood-lot should be prudently managed, and made to last as long as possible. There are few, if any, parts of the country to which this advice is not applicable, now that the consumption of our forests by increasing population and extending railroads is rendering firewood a valuable market article all over the land. The days of reckless cutting, slashing and burning, it is to be hoped, are over for ever. Little as some think it, the time is not far distant when we shall find it needful to replant forest trees in localities where but a few years ago there was prodigal waste of timber, while it was abundant. Not only firewood, but fence material, should be got out in winter, for use in early spring, where new fences require to be built, or old ones need repair.

When out-door work cannot be done, in-door jobs may well claim attention. There is what the Irish labourer calls "ridding up," or what Mrs Stowe's "Aunt Chloe" styled "claring up." An air of neatness should characterize the barns and stabling. If there are boys or hired men about, they are apt to display a wonderful faculty for getting things into disorder and out of place. Every now and then the places they haunt will need putting to rights. The law, "a place for everything and everthing in its place," will often be more honoured in the breach than in the observance. Nevertheless, every effort should be made to have it obeyed. Farmers who have tools and a shop of some kind, may improve winter leisure by making racks, gates, rollers, drags, and a variety of other articles that will be in request when the busy season comes round again. This, too, is the time for balancing up farm accounts, taking stock of the year, considering the improvements that may be made on past operations, and laying wise plans for the future. The long evenings are favourable, for reading, for attending farmers' clubs, for making social visits, and for indulging in home recreation. A moderate amount of time may very properly be given to innocent entertainments by which the spirits are enlivened, and the powers of body and mind freshened for a resumption of the stern business of life. There is no reason why winter should be either a dull or an idle time.

Last, but not least, early winter is the time for renewing subscriptions to Agricultural journals, and making efforts to extend their circulation, and we take the opportunity of urging both these duties on the readers of the CANADA FARMER. Prompt renewal of subscriptions is important, that there may be no intermission of its visits to the homes where it is a regular and, we trust, a welcome visitor, while one of the best ways of promoting the advancement of agriculture is to induce as large a number of persons as possible to take a journal whose constant aim is "to improve the soil and the mind." As will be seen by the Prospectus which we publish on our last page, a new series will begin on the 1st of January, 1869, when certain changes will be made, which will, we doubt not, be considered as improvements, and help to augment the popularity and usefulness of the CANADA FARMER.

The Field.

The "Early Rose" Potato.

To the Editor of THE CANADA FARMER:

SIR,—Your extract from the *Practical Farmer*, in your issue of November 1st, relating to the "Early Rose" potato, reminds me of our success with this new and valuable seedling. We procured this last spring, from Messrs. B. K. Bliss & Son, of New York city, one and one quarter pounds of "Early Rose," costing, with postage, $2 50. The tubers were cut as nearly as could be into one-eye pieces, and were planted from eighteen to twenty inches apart, alongside and in the same soil as our common garden varieties. The plants were almost dried up during the period of our unprecedented drought; but the rains of August had the effect of renewing their growth, which continued till the vines were killed by the frost. Hence no idea could be obtained of their *earliness*, or time of ripening. The potatoes were taken up September 29th, and weighed. They yielded *one hundred and twenty-five pounds* (125 lbs.) *to each pound planted.* We have no doubt the yield would have been much larger had the season been an ordinary one; but it was enough to show what an enormously productive potato the "Early Rose" is. Parties who have tried the "Early Rose" this season report generally of from one to *eight bushels* from the pound of seed.

The potatoes were all of good size (few or no small tubers), many weighing one pound and a quarter each. The great yielding qualities of the "Early Rose," its early ripening, producing marketable potatoes in eight weeks from planting, its fine table quality, its good size and shape, having full eyes, even with the surface of the tuber, and fine appearance—in these last respects being the best of all of the fifteen varieties in our cellar—go to produce a potato of great value.

We also tested, this past season, the principal Goodrich seedlings, from seed procured from original sources, in New York, the results of which are so extraordinary that we shall send an account for publication before next season. Suffice it to say here, that the "Early Goodrich," one of the best, if not the most valuable of the Goodrich seedlings, produced at the rate of 300 per cent more than the common "Reds"—the variety raised in this section for the main crop—and 200 per cent more than "Californias" or "Rocky Mountain" variety, a coarse potato of little value, except for stock feeding, and the largest yield cultivated here. All the varieties were grown on the same soil, and received the same culture in every respect, the object being to get an idea, as near as could be, of their comparative values.

L'Orignal, Ont., Nov. 11th, 1868.

Productive Vermont Farm.

THE Newport (Vt.) *Express* gives the following account of a farm in Derby, on the north line of the State of Vermont, near the Canada border:—

Last summer we spoke of the hay crop of Emora Kingsbury, Esq., of Derby, amounting to nearly eleven tons on a little less than one and three-fourths acres. This was cut June 24, and consisted of timothy, red and white clover; the timothy not headed, and the red clover not all in blossom. Mr. K. now informs us that his second crop on the same piece, cut Aug. 3rd, was 6,188 pounds, or a little over three tons, making the total yield from one and three-fourths acres ten tons, or five and three-fourths tons to the acre. Mr. Kingsbury has scales set in his barn, and weighs all his crops, as well as his stock before and after fattening, and after slaughtering, so that he is able to tell exactly what he is doing, and the results of all his operations.

We were so much interested in Mr. K.'s account of his hay crop, that we have provailed on him to give us some further details of his farming. His farm consists of 192 acres, 40 of which are in pasturage. His corn crop was quite as remarkable as his hay. From 163 rods he has harvested this fall 254 bushel baskets of ears. One basket of this corn, when shelled, made eighteen quarts. This would give a yield of one hundred and forty-two bushels of shelled corn on two rods more than an acre of ground. In reply to our inquiry as to how the land was prepared for the crop, Mr. Kingsbury stated that last year he grew oats upon it with a light dressing of manure; this year he spread a compost of potato tops, cut cornstalks and straw (upon which he yarded his cows last summer), and which was thoroughly rotted; harrowed this in, furrowed four feet apart for the rows, and made the hills a little less than three feet apart in the row; into each hill he put a shovelful of muck on which he had yarded his hogs. Thorough cultivation did the rest. The variety he cultivates is a long-eared 12-rowed sort, which he thinks as early as the smaller kinds, more productive, and yielding a much greater quantity of forage. He says he had by actual weight from the above field 15,360 pounds of fodder, and that this fodder alone is worth as much as the corn and forage together from the same breadth of Canada corn. Last year, from one and one-eighth acres, he raised 237 bushels of ears, and over seven tons of fodder.

Mentioning some other large yields, Mr. Kingsbury stated that in 1860 he raised 762 bushels of oats on nine acres; and in 1866, 531 bushels on seven acres—the first-mentioned crop weighing 35 pounds, and the last 36½ pounds per bushel. Of Jackson white potatoes, Mr. K. has raised this season 192 bushels on 77 rods—one potato weighing 2¾ pounds.

Mr. Kingsbury uses no artificial fertilizers on his farm, relying on his muck beds, his composts and his stock, to produce everything necessary to enrich his land.

While talking over the subject of exact weighing and measuring, and their importance to the farmer, Mr. Kingsbury alluded to the shrinkage of beef cattle and hogs in slaughtering, and gave us a few figures from his books to show that this shrinkage is usually overrated, especially by drovers and dealers. Four fat hogs killed by Mr. Kingsbury shrank 12½ per cent., or one-eighth. Two cows killed Dec., 1866, shrank—one 32 per cent. and the other 37 per cent. A four-year-old heifer killed Dec., 1867, dressed 987 pounds, and shrank less than 28 per cent. The figures are worth remembering.

Irrigation of Meadow Lands.

THE advantages and practicability of irrigation are being considerably discussed. The *Utica Herald* gives the following account of the results of the plan practically carried out:—

"Mr. Emey Allen, of West Turin, Lewis County, N. Y., who has a beautiful farm of some 335 acres lying along the foot of a range of hills, has practised irrigation upon his meadows for some years, and with excellent success. He has 100 acres of meadow in one field, the surface quite level, over a considerable portion of which the water is carried in the spring. This meadow lies at the foot of the hills, and streams come down and enter it at different points. In the spring the melting away of the deep snows from the hills and lands above, furnish a large amount of water, which is spread over the meadow, and all fertilizing matter mingled with the water allowed to settle upon the soil. The meadow is not naturally wet, but is dry enough for the plough. The soil is deep and of remarkable fertility, and by a judicious system of irrigation, is made to yield large crops of grass.

Quite a number of acres of the irrigated portions have never been ploughed, the hillocks and uneven surfaces having been levelled with the spade. Mr. Allen estimates the crop of grass grown upon the meadow the present season at 300 tons. We went over this meadow and found it covered with a luxuriant growth of herbage, the whole presenting one of the finest pieces of grass land that we have recently seen.

Mr. Allen says his average yield of hay from 120 acres of meadow, for a series of years, has been, one year with another, not less than 250 tons per year.

Last winter his stock consisted of fifty-seven canal horses, five work horses, two yoke of cattle, twenty-six cows, five two year old heifers, seven yearlings, and twenty-seven sheep, and he sold and drew off twenty-six tons of hay, having several tons left over.

We should have remarked that forty acres of this meadow have never received a portion of manure, but have been kept in a high state of fertility, solely by irrigation. The water is let on very early in spring, and is about three weeks in working itself off. The annual product is about three tons per acre. The grass here is cut but once during the season, and the after-math is fed off in the fall, but never allowed to be closely cropped. Mr. Allen thinks he would get a finer quality of grass by feeding the meadows in spring, say till about the twenty-fifth of May. The grass is mostly timothy, clover and red top, though of course largly intermixed with native grasses. When Mr. Allen's father came into the country and settled here in 1797, the whole country between Turin and Kingston, Canada, was a dense forest, in which no timber had been cut."

How to Kill Wild Oats.

To the Editor of THE CANADA FARMER:

SIR,—The following plan has been found very useful in eradicating wild oats. Plough the stubble early in the fall, and harrow well. Cross plough early in the spring, and after a few days harrow well. About the latter end of May, plough a third time and sow with barley.

This mode of cultivation will do much towards germinating and then killing the foul seed. But should wild oats still appear, there is one more chance. Barley will ripen in time to harvest when the "oats" are yet green, so preventing the seed from shaking off to pollute the land for another year.

Several farmers of my acquaintance have tried this method and found it good.

ROBERT BROWN.

Garafraxa, Nov. 18th, 1868.

Unprofitableness of Hop Farming

OUR American exchanges are comforting unfortunate hop-growers by the publication of the following paragraph from Mr. Caird's, "English Agriculture," in reference to the culture of the hop in Sussex, England, where from 10,000 to 12,000 acres are usually occupied by this crop:—

"This plant requires the richest soil of the farm, and receives nearly all the manure produced, robbing the corn and root crops of the share which rightfully belongs to them. The farmer's attention is concentrated on his hop garden, and the rest of his farm receives very little of his regard, and hardly any of his capital. The operation of the duty gives the business a gambling character. A favourable season, with a large yield of hops, is disastrous to the farmer, as the market value of the article falls, while the duty swells in proportion to the lucky character of the crop. When the crop is a short one the farmer prospers, as the price of the hop rises and the total amount of the duty falls. There is thus a constant succession of chances, extraordinary prices being sometimes realized, which tempt men to further adventure and withdraw them from that steady, persevering industry, without which agriculture cannot be profitably carried on. The uncertainty of prices and crops, and the peculiar bearing of the duty, are such that very few of the hop farmers are enriched by it, many are ruined, and still more are kept on the verge of bankruptcy. It is very probable, therefore, that if the cultivation of hops were to cease, it would in the end be no loss to the Sussex farmer, as his richest land would then be released for the growth of crops of a less hazardous kind, and the rest of his farm receive a fair share of manure and cultivation."

Loss in Stacking Hay.

A FARMER of sound judgment, and large experience in cutting and storing hay, estimates his own loss in stacking at twenty-five per cent. He cuts probably a hundred tons a year, and stacks a fifth part of it for want of barn room. He has very properly made up his mind to build a new barn. We think his estimate is not wide of the mark. There is a large loss from moulding at the bottom of the stack, and old rails, boards, or straw, will not wholly prevent it. Then the whole external surface for three to six inches is weather-beaten, and loses much of its sweetness, and it is not improbable that this loss of aroma extends through the whole stack. The conviction is universal among intelligent men, that barn-stored hay is worth much more than that which is taken from the stack. Why then follow this wasteful practice? Look at the great loss to this farmer who cuts one hundred tons of hay, worth $2,000. According to his own estimate, he pays $100 a year for the privilege of stacking one-fifth of his crop. This is but a small part of the loss where the hay is fed out at the stack. It costs at least a third more hay to keep cattle without shelter. These are strong arguments for more barn-room.—*American Agriculturist.*

Stump Pulling.

To the Editor of THE CANADA FARMER:

SIR,—Some fourteen months ago I inquired, through the columns of your valuable journal, for a screw stump machine, and received the desired information. I purchased one of the above-named machines for about $175. This machine requires three men to clean the stump while being raised; one horse to wind it up; also, one yoke of oxen to move it from one stump to another. On an average, we can pull eight pine stumps per day. In looking over the last number of the CANADA FARMER I see an account of a machine, called the "Pioneer Stump Puller," exhibited at the N. Y. State Fair by C. H. Church, of New Berlin, Chenango County, N. Y," which is said with "two men will raise a weight of 25,000 pounds, and pull 100 stumps a day." If that is so, it puts my machine in the shade altogether. I would like to see a draft of this "Pioneer Stump Puller," and have a full explanation of the same. I think it would pay any person or persons wanting a job of pulling stumps to purchase one of these machines, as I have from two to three thousand stumps to take out, which I will let in lots of from fifteen to twenty-five acres.

I have been paying from sixty-five to seventy-five cents per stump, that is, for pulling and burning off, leaving the land ready for cultivation. Any person or persons wanting a job on the above-mentioned terms can have it by applying to

THOS. BURNHAM.

Sandford, Nov. 6, 1868.

NOTE BY ED. C. F.—Our correspondent had better write for further information to the manufacturer of the "Pioneer Stump Puller," who most likely has an illustrated descriptive advertisement or circular of the machine in question.

Cost and Profit of a Root Crop.

To the Editor of THE CANADA FARMER:

SIR,—At this season of the year one often hears the question asked "whether root crops really do pay;" and as they are certainly becoming daily of more importance in Canadian agriculture, it is probable that many would give them a trial, were they not deterred from doing so by the seemingly enormous cost attendant thereon. If, therefore, some of your readers who have been in the habit of cultivating this crop, would give their experience of the cost per acre, I think it would be conferring a benefit on the farming community.

I append hereto my own estimated cost per acre of a crop of turnips.

Rent	$4 00
Seed, 3 lbs., at 30 cents (say)	1 00
Ploughing twice	4 00
Cultivating, harrowing, &c.	2 00
Hoeing twice	10 00
Pulling	2 50
Carting	2 50
Manure—20 loads at 50 cents	10 00
Carting, spreading, &c.	10 00
	$46 00

There is, besides, the expense of making the drills and putting in the seed. If I am correct in the above estimate, nothing short of an extra crop will balance the cost.

DEWDROP.

Hamilton, Nov. 20th, 1868.

CHOPPING.—A correspondent criticises "Mark Tapley's" directions for using an axe. He takes exception to the weight of the axe recommended, 3 lbs., as the best choppers in his locality usually prefer one weighing about 4 lbs. The length of the chip directed to be taken out, three feet for a tree four feet in diameter, is objected to as out of all proportion, and an impossibility if it is only commenced at the height specified. "Mark Taplcy's" description is no doubt somewhat ambiguous and inconsistent, and there is a manifest error in regard to the weight of the axe-head.

A Table of Dimensions of Dry and Liquid Measures.

THE following useful table is supplied by a correspondent of *Colman's Rural World*. It will be found convenient in making calculations of quantities, or in extemporizing measures when required, by constructing a box of the right dimensions.

DRY MEASURE.

Measures.	Square Vessel. No. of Cubic Inches.	Length.	Breadth.	Depth.	Round Vessel. Diameter.	Depth.
Barrel	10762.0	22	22	22 7-32	23	26 7-8
Bushel	2150.4	13	13	12 3-4	18 1-2	8
Peck	537.6	8	8	8 6-16	10	6 13-16
Gallon	268.8	7	7	6 1-2	7	6 61-32
Quart	67.2	4	4	4 3-16	4	6 11-32
Pint	33.6	3	3	3 3-4	3 1-2	3 1-2
Gill	8.4	2	2	2 3-32	2	2 21-32

LIQUID MEASURE

Measures.	Square Vessel. No. Cubic Inches.	Length.	Breadth	Depth.	R'd Vessel. Diameter.	Depth.
Barrel	7275.5	20	20	18 3-16	21	21
Gallon	231.0	6	6	5 6-16	7	6
Quart	57.75	3 3-4	3 3-4	4 3-32	4	4 19-32
Pint	28.87	3	3	3 3-16	3	4 1-16
Gill	7.22	1 7-8	1 7-8	2 1-16	2	2 9-32

☞ On Mr. Mechi's farm in England, which contains 170 acres, there are 72 acres in wheat and 18 in pasture. This is a leased farm, yet Mr. Mechi used £16, or nearly $80 in gold per acre, and would have preferred to have increased this to £25. He made 18 percent. profit.

NORWAY OATS.—A variety of Oats under this name has been extensively advertised and extravagantly lauded. Considerable dissatisfaction has, however, been expressed among our neighbours in the States, in regard to the true merit of the variety, and the advertisers are charged with endeavouring to put a fictitious value on a very ordinary grain.

CRANBERRIES IN UPLAND.—A correspondent of *The Rural American* says:—"My own experience, and that of many others, is proof conclusive that they can be grown successfully and profitably on dry uplands. A clay or loamy soil, that is naturally moist, is the best. Upon such there is no doubt of successful culture. The land should be prepared by ploughing and harrowing thoroughly; rake level, and plant in rows 1½ feet apart, and one foot in the rows. Hoe the plants as long as convenient without disturbing them, after which weeding is all the cultivation necessary. The plants are set in spring until the 15th of May; in the fall, from the 1st of October until the ground freezes. On the pine-barren lands of Long Island they grow to perfection without the usual course of flooding, which so many consider necessary.

THIN SOWING.—The accompanying letter is from a practical farmer, who for many years has occupied a 700 acre farm in West Norfolk. My best field (one bushel seed) yielded 7 quarters 2 bushels per measured acre of fine white wheat (Club-headed Rough Chaff); sold for 60s. per quarter. My whole wheat crop (73 acres) will average 6 quarters per acre. The peck an acre yields 2 bushels per acre less than the adjoining 1 bushel, which was over 6 quarters of white wheat per acre. The peck an acre was put in as late as the 20th of November, which I do not recommend, but was determined to put it in same day as the rest.—*F. F. Mechi, Tiptree, October*, 1868.

The following is the letter of Mr. Mechi's correspondent:—"Oct. 13, 1868.—At the request of my brother, I write to inform you of the result of my experience in thin sowing for wheat last year. From what I saw on your farm, and what I read in your publication, I was induced to try 4 pecks per acre in four different fields. As you may suppose, my labourers laughed at the idea of it. I need not tell you that the ridges selected for the purpose were very visible all winter, even before you got near the field; looked very thin. As soon as the plant began to grow in the spring, it told us what it was going to do. I had a few friends to look at in the summer, and I think I may say that every one was in favour of the thin sowing, both as to straw and corn,—that is to say, 4 pecks against 7 pecks per acre, which is my usual quantity. I had that which grew in one field cut by itself; also the adjoining ridge, each containing 3 roods and 36 perches. The 4 pecks per acre gave me 13 coombs and 2 pecks. The 7 pecks per acre gave me 11 coombs 3 bushels and 3 pecks. I shall try it again this year."

THE MANUFACTURE OF MANURE.—Many of our farmers complain that they cannot make enough manure, and I never yet found a good one who has had too much. Now I think that if a farmer has hay enough there need be no difficulty in obtaining enough manure.

We see many of our barnyards constructed with escape holes in the wall along the lowest side of the yard, and from these holes a passer-by can scarcely fail to notice the very essence of manure escaping. The most valuable portion of the manure are those which are soluble, and of course these are taken up by the water in its passage through the manure and out of the yard.

Not long since I was arguing with one of my neighbours upon the propriety of stopping up these holes in his barnyard wall, when he met my objection with the assertion that he could not keep his yard clean enough to keep cattle in. A further investigation showed that his yard was not supplied with rain spouts, and consequently there was more water in the yard than fell there in direct descent. Yet this same farmer would complain that he "could not make manure enough," and this, too, when the most valuable portion of what he did make was escaping into the public road and into his neighbor's land.

If no more water finds its way into the yard than that which falls into it, there should be no difficulty in keeping it clean with the materials found on a common farm, such as coarse grass from the swamps and lowland, soda from the roadside, tussocks from the meadows, whose removal, while it benefits the manure pile, also improves the appearance of the meadow. If these are all used up, then it will be time enough to complain of the difficulty of not being able to make manure.—*Correspondence Germantown Telegraph.*

FEEDING OFF AFTERMATH.—It is a very common practice with farmers to reserve their meadow feed until very late in the fall, even so near to the winter that the frost has taken nearly all the succulent and nutritious properties out of it; but, by this mode of management, very little benefit is received, and in many cases great injury is done. Some advocate, however, that aftermath should not be fed off at all, but left as a shield and mulch for the roots; but from our own experience, we do not believe meadows are injured by being pastured in the fall, if it is done at the right time and by certain animals.

Meadows are injured by horses and sheep late in the season; for after the blades of the grass are killed, these animals will nip close to get sweet feed. They never should be allowed upon mowing land after the grass has stopped growing, not even in winter when the ground is frozen, for they will then gnaw to the very roots.

Horned cattle are really the only fit animals for the meadow, and they should be turned in while the feed is good, and removed as soon as the earth becomes moist enough for their feet to break the sod. In this way a profit may be derived on one hand, without any loss attending on the other, and sufficient protection left for roots. Timothy, and many other grasses which are common, take strong hold upon the soil, and are difficult to eradicate, and for this reason farmers abuse their fields.

Close feeding kills out here and there a little, and mosses, with other foreign matters, work in so gradually that it is for a few years hardly noticeable, but eventually the meadow has to be ploughed and restocked, because a paying yield of grass is not received.

Now, all this results from injudicious management; for we know of many meadows which yield heavy crops every year of the best quality of grass, that have never been ploughed or re-seeded since the land was cleared, nearly half a century ago. They have always been pastured in early fall, never fed close, and have occasionally received a top-dressing of barnyard manure.—*Ohio Farmer.*

Stock Department.

"Wharfdale Rose."

ANNEXED is an engraving of "Wharfdale Rose," a yearling heifer of great beauty and promise, imported by M. H. Cochrane, Esq., of Compton, Quebec, at the same time as "Duchess 97th," who lately figured in our columns. Both these animals were purchased of that noted breeder of Short-horns, Capt. Gunter, and by a comparison of their pedigrees it will be seen that they were sired by the same bull, and that, on the female side, the heifer now illustrated comes of no mean stock. "Wharfdale Rose" deservedly took the highest honours in her class, both at our own Provincial Exhibition and at the New York State Fair. One of the best judges of Short-horn cattle in the United States, Mr. Sanford Howard, writing to the *Country Gentleman*, says of "Wharfdale Rsoe,"—"This is a very promising animal generally,—well shaped and clean fleshed." The following is her

PEDIGREE.

"Wharfdale Rose," roan, caved September 27, 1867; bred by Capt. Gunter, Wetherby Grange, Yorkshire; got by "3rd Duke of Wharfdale," 21619, roan, bred by Capt. Gunter. Dam "Oxford Rose," red and white, sired by "6th Duke of Oxford," 12765, roan, bred by W. Tanqueray; gr. dam, "Moss Rose," got by "Ravensworth," 9532, roan, bred by W. Emerson; g.g. dam, "Graceful," got by "Freebooter," 7025, roan, bred by the Earl of Carlisle; g. g. g. dam, "Treasure," got by "Garthorpe," 2049, roan, bred by the Earl of Carlisle; g. g. g. g. dam, —— got by "Belshazzar," 1704, roan, bred by the Earl of Carlisle; g. g. g. g. g. dam, —— got by "Don Juan," 1923, roan, got by "Meggen's Bull," &c., &c.

"WHARFDALE ROSE,"
The Property of M. H. COCHRANE, Esq., Compton, Quebec.

The Compton Short-horns.

WE are glad to learn that some valuable additions have recently been made to the Compton herd of Short-horns, and that the importations made from England during the past summer are thriving on Canadian soil. The fine Booth heifer, "Star of Braithwaite," bred by Mr. Brewer, of Yorkshire, for which Mr. Cochrane paid 250 guineas, has lately dropped a fine roan bull calf, sired by Mr. Carr's bull, "Prince of the Realm," (13510); "Star of Braithwaite," by "Baron Booth," (21212); dam, "Star of Windsor," by "Windsor," (14013); gr. dam, "Vesper," by "King Arthur," (13110.) Our readers who are familiar with the English Short-horn Herd Book will know how to appreciate such a pedigree. The noble cow "Rosedale," after some weeks of knocking about on the cars, attending a number of exhibitions, and reaping a rich harvest of honours for herself and her owner, had been but a few days in her byre at Compton, when she gave birth to a rich roan heifer, sired by the "11th Duke of Thorndale." Both "Rosedale" and her calf are doing well. Mr. Simon Beattie, in a note received the other day, says, "Rosedale" is looking as gay and vigorous as a three-year-old heifer, and is as light on her feet as a fawn, thus giving proof of the strength and stamina of the Booth cattle. The "11th Duke" gives every promise of being a most valuable stock bull. Such of his progeny as have made their appearance at Compton, to the number of four—three heifers and one bull—are every way satisfactory as to quality, colour, and general characteristics. Mr. Cochrane has also bull calves from two other imported dams, both doing and promising well. One is from Mr. Harvey's "Walton on the Hill," got by "Lord Wild Eyes 5th;" dam "Wild Eyes 26th," by "Lad of Walton," (17787); gr. dam "Wild Eyes 24th," by "4th Duke of Oxford," (11387), &c. This calf was dropped a few days before leaving England, and is a fine, strong animal. The second is from Mr. Brewer's other heifer by Mr. Carr's "Prince of the Realm," (13510); dam "Pink Thornleaf," by "Baron Booth," (21212); gr. dam "Windsor Lavender Leaf," by "Windsor," (14013), &c., &c. This calf was born on board ship during the voyage from Liverpool to Canada, and is a perfect type of a Booth bull. We congratulate Mr. Cochrane on his good fortune thus far, and hope he may have a good run of it, with the choice animals he has obtained at so much cost and trouble.

"Gems from the Report of a Sheep Show."

UNDER the above heading, we find in one of our British exchanges the following "gems," culled from a report given by one of the Dublin dailies, of a Sheep Exhibition, lately held in that city. The name of the journal in which they first appeared is not given, but it is remarked that the subjoined extracts bear a strong resemblance to a report of a Royal Agricultural Show in the *Irish Times*, which descanted in a similarly lucid style on what were designated, "The eventful events of the past week." Evidently all the high falutin reporting is not done west of the Atlantic. Here are the "gems":—

"1. Root crop cultivation received such an impetus from such exhibitions that the models of the tiny roots then grown, contrast so diminutive with the creditable samples now being yearly staged within its walls, that the most superficial observer can at once perceive the *magnitude of the comparison.*

"2. The old Irish cow, whose tediousness to fatten or mature, and whose *usefulness*, in a pecuniary sense, to the owner was comparatively *worthless*, has been now *substituted by* those valuable animals of improved breeds which any casual observer cannot fail in discerning throughout the farmerics of the country.

"3. The subject of sheep breeding in Ireland has recently assumed a very *undivided state of opinion.*

"4. The most important feature in connection with the exhibition just being held is that *breeders* and admirers of sheep, of all shape and lineage, *have been placed in such proximity* that a rare opportunity is thus afforded to all, to see placed within the precincts of the agricultural hall all descriptions sheep of the different sorts.

"5. Every attempt to *improve* and perpetuate a *more improved* or judicious class of the ovine tribe was most *transparent* throughout the day. Graziers, exporters, importers, and the general farming community, seemed alike anxious to possess themselves of exchange, or hire out the *services* of their celebrated ram *sheepwalks* as suited the country."

Weaning Colts.

THE following communications have been received since the last article on the same subject went to press, and were not in time for the CANADA FARMER of Nov. 15th. They are based on the experience of practical men, and we give them to our readers that they may be enabled to compare notes. The first letter is as follows:—

"*To the Editor of* THE CANADA FARMER:

SIR,—In your paper of the 2nd instant, an inquirer, 'Gosford,' says 'if any of your correspondents practically acquainted with a good way of weaning colts would give the benefit of his experience through your columns he would confer a great favour.' Now, although not heretofore a correspondent, I will venture to give my experience. In the first place, I aim to take the common sense view of everything. I put the colt in a good pasture, and if I can do so, I give some company that it is acquainted with. But, at at any rate, I put the mare in the adjoining field; then they both feel as if they were not separated, and do not wear off any flesh by anxiety and running. And I take the mare in to the colt twice a day, for two or three days, and let it suck. After that, I let it suck once a day, for two or three days; then I let it suck every other day for two or three days, and if necessary to dry up the mare, I will perhaps let it suck once or twice in the course of the next week. By that course the colt will get weaned and the mare will be dried up, and neither of them lose flesh or be punished, which is both to my interest and their mutual comfort. If my experience is of any service in weaning colts, I will some time give my experience in breaking them, in which I also take the common sense view.

Wilton, 9th Nov. 1868. H. P."

Another subscriber writes:—

"In answer to the query respecting weaning colts, I beg to submit the following note. There are various ways in which they may be weaned. I think as good a way as any is to take them from the dam and tie them in a stable by themselves, with strong halters, and give them milk from the cow, which they will take the second or third time it is offered to them, if they get no water. You may give them milk and water as suits. Afterwards, give a few oats, and all the hay or green clover they can eat, when it can be got. At the end of seven or eight days, lead them out to the field at noon, and take them in at night (there must be good fences to keep them in). By doing so, you will soon have them to lead like old horses."

Canadian Natural History.

The Wolverene.

(*Gulo luscus.*)

THE settlement of the country has driven entirely away from many localities animals that were once common, and among the creatures that have almost disappeared from the neighbourhood of man is the Wolverene; though several times lately accounts have been published of its intrusion into dangerous proximity to human habitations. It is one of the larger members of the group of animals with which it is most closely allied, but, though extremely voracious, is by no means so formidable as it has been popularly supposed to be. It is a carnivorous animal, and feeds principally upon the smaller quadrupeds. Its general appearance is not unlike that of a small bear. Indeed, Linnæus and some other naturalists have placed it in the same family (*ursidæ*), but it is more properly classed with the weasel tribe (*mustelidæ*), of which the more common Canadian representatives have been noticed in recent numbers of the CANADA FARMER.

The Wolverene is an inhabitant of Northern America, Siberia, and a great part of Northern Europe, its geographical range extending from 42° to 75° north latitude. The ordinary length of the full-grown animal is about two feet, exclusive of the tail, which is about six inches long. The general colour of the fur is a brownish black; the nozzle is black as far as the eyebrows, and the space between the eyes of a brown hue. The body is stout and compactly made, with an arched back, and but little elevated from the ground, the legs being short. The head is small, round and broad, suddenly diminishing to the nose. The ears are nearly concealed by the fur. The eyes are small. The fur is loose and shaggy, of a brown tinge, deepening into black, especially toward the extremities, the paws being quite black, and the contrast between the jetty fur of the feet and the almost ivory whiteness of the claws is extremely curious. A paler tinge of colour, sometimes almost whitish, is observable on the chin and between the fore legs. A broad band of light chestnut extends along the flanks, meeting its fellow of the opposite side near the root of the tail. This appendage, like the feet, is black, and shaggy with long pendulous hairs. The toes, five in number, are distinct, with long, hooked claws. The paws are very large in proportion to the size of the animal, and it is supposed that this modification of structure is intended to enable the Wolverene to travel over the snow.

This animal is perfectly at home among the branches of trees, and although not apparently very active or alert, it will retain its hold and drop or leap from a considerable height with ease and security. It is much detested by trappers, as it follows them, and is in the habit of detaching the bait from the traps. By its keen scent it also frequently discovers the storehouses of provisions, or "caches," as they are called, which the provident hunters lay by, in order to fall back upon in case of bad success, and robs them of all animal food that it can find.

The Wolverene is not a very prolific animal, as it seldom produces more than two at a birth. The young have a uniform downy cream-coloured fur. The nest is frequently placed in the crevice of a rock, or in some secluded situation, and the young Wolverenes make their appearance in May.

Salmon Culture in Ontario.

IN the number of THE CANADA FARMER for March 1st, 1867, we gave an account of Mr. Wilmot's experiments in propagating salmon, and described at some length the usual method of conducting the process of artificial fish-hatching. It will no doubt be interesting to many of our readers to learn what progress has been made by Mr. Wilmot in his interesting and important enterprise. In bringing the matter once more under notice, it may be well to refer to the circumstances which led to the undertaking, and to describe again the changes that take place from the birth to the maturity of the fish.

There was a time, not many years ago, when the

tributary creeks and brooks of Lake Ontario and the St. Lawrence were the homes and native waters of countless shoals of salmon. From the Gulf of the St. Lawrence to the Falls of Niagara, these splendid fish were in rich abundance, yielding a full harvest to all who would gather it, and serving as a bounteous garner from which white man and Indian could draw with unsparing hand for summer food and winter store. As civilization, with its accompaniments, mills, steamers, and manufactories, spread, so the salmon decreased; and as the salmon decreased, so ill-advised and ignorant men became keener in their pursuit, destroying the fish at those times when they ascended the streams to breed. Year by year the shoals became smaller in size and fewer in number, until the time arrived when the once fertile streams became barren, and localities in which salmon could be found in thousands, produced perhaps half a dozen. An Act was passed by the Legislature for the better protection of the natural and artificial breeding of fish, but, though this is a very excellent measure, it is but one step in the right direction, for the harm has been done, the fish are gone, and the wealth that lay by our hand is departed, if not for ever, at least until some method is arranged for its reorganization and protection.

This is a matter, the importance of which cannot be too strongly insisted upon. It touches the interest of every town and village along the shores of the Lake, and appeals directly or indirectly to every commercial man throughout the Province. Every farmer and settler in the country is affected by it in one way or another, and the whole community suffer by its neglect, and benefit by its being cared for. Knowing that every ray of light thrown upon the subject tends to its welfare, and feeling that every effort of private enterprise redounds to the public good, we speak with the greatest pleasure of the admirable pisciculture establishment in our own neighbourhood, which we have just inspected.

Mr. Samuel Wilmot, of Bowmanville, on the shore of Lake Ontario, has watched the streams in his neighbourhood becoming gradually depopulated; and remembering them when they were, so to say, alive with salmon, he determined to make some effort to restore the fish to their former abundance, feeling confident that with the forbearance and assistance of his neighbours, a sensible improvement might be made in the course of a very few years. His first attempt was conducted on a very limited scale, but being satisfactory, he enlarged his operations with each successive season, until his labours are now beginning to show most gratifying results. In order that the reader may better understand what has been done, as well as what is doing, and see clearly the perfect method of Mr. Wilmot's salmon nursery arrangements, we will explain shortly the changes undergone by a salmon from the earliest period of his existence until that time when he becomes the terror of smaller fish, and the lawful object of man's chase. It is a well-established fact, that when their spawning time arrives, salmon will almost invariably seek those streams in which they themselves were hatched. Travelling up stream, the female salmon, accompanied by her mate, selects some shallow, gravelly bank on which to deposit her ova. In this both male and female fish dig furrows, using their tails for that purpose, and not their noses, as is very commonly believed. In these furrows the female lays her eggs in the ratio of about six hundred to every pound of her own weight, and over these the male fish deposits his melt or impregnating fluid. They then cover the furrows with the surrounding gravel, and leave the eggs to the effect of time and the running water. This occupation requires from three to twelve days, according to the condition of the salmon and the surrounding circumstances. The eggs, unless disturbed by the action of the stream, or the depredations of birds, or other enemies, remain for a length of time, varying from ninety to one hundred and thirty days, according to the temperature of the water, at the expiration of which period the young fish make their appearance. It must be remembered, however, that these eggs are the prey of innumerable foes; ducks, kingfishers and water lizards hunting them out and devouring them wherever they can be found. As the banks wherein they are laid are in the shallow parts of the water, and easily distinguishable by the bright appearance of the gravel, they are readily found, so that an almost incredibly small per centage of the eggs deposited by a shoal of salmon are ever brought to life. Added to this is the damage done by every

frechet, which disturbs the banks and destroys the ova. When the fish first emerges from the egg, he is called an alien, and is an ugly little creature, with a dispro portionately large head, and an unpleasant looking excrescence attached to him at the point where his gills should be. This is called the umbilical bag, and contains the food that sustains him until he has absorbed the whole thing, when he becomes marked with dark spots, and is then in his second stage, and is called a "Parr." For about twelve months he remains in the pools and shallows about the district of his birth-place, during which time he grows to the length of four or five inches, and changing into his third stage becomes a "Smolt." It is in this phase of life that he experiences the instinctive desire to reach the sea, and takes his departure, usually in the spring of the year, to return in the autumn as a grilse. So rapidly do salmon grow at this period of their existence, that a smolt weighing a few ounces, and measuring four and a half inches long, will return from the sea, after an absence of a few months only, weighing three or four pounds, and measuring about fifteen inches in length. In this stage he is capable of performing the functions of a male fish, although, strange to say, his mate is usually a female *salmon*, as few female *grilse* return to spawn. Migrating once more when the spawning season is over, the grilse returns a full-blown salmon. This is, of course, assuming that he escapes the thousand and one dangers that beset his way between the ocean and the stream, the stream and the ocean. Many salmon return to the shallows scarred with wounds inflicted by other fish, and marked with the salt water parasites, which cling to them in the ocean, but which are discarded on coming into fresh water.

Encouraged by the Legislative Act that made the taking of salmon from a breeding stream a punishable offence, Mr. Wilmot commenced his operations in the fall of 1866 by hatching a small quantity of salmon ova in his own kitchen. The fish from these he turned into the creek, and then gave his attention to utilizing the stream itself, in which, at this time, there were hardly six grilse to be seen. In the following year there were not more than a dozen; but in the present year no less than one hundred and fifty grilse have made their way into a portion of the water set aside for them; besides a number of others that remain outside in the body of the creek. These one hundred and fifty must therefore have been from the number turned into the stream in the fall of 1866, for those were now due according to all the calculations and deductions of pisciculturists, and up to the time of their appearance the stream had produced but a mere handful. This shows very conclusively what a little fostering care can do towards restocking our waters; for were these grilse the result of natural breeding, they would represent a deposit of between a quarter and half a million of eggs. This proportion may at first sight appear large, but is by no means exaggerated, and it can be easily comprehended by any one who considers the innumerable dangers that beset the young of the salmon. Not only are the eggs frequently lost by the effects of heavy rains and the depredations of birds, beasts and insects, but the young salmon has a distance to travel of over a thousand miles, during which time he is the prey of innumerable enemies, not the least formidable of which are the larger fish of his own kind. The existence of any creature must be precarious that lives in constant danger of being devoured by its own parents.

The plans which Mr. Wilmot has adopted for producing salmon and protecting the young fish, before they take their departure for the sea, are as perfect as they are simple, and are in beautiful harmony with the habits of the fish and the nature of the country. His nursery grounds are about a mile and a half from the lake, and are situated in a small stream, rapid and shallow in some parts, and deep and still in others. An artificial breakwater has been built at one point of the stream, and is so arranged that salmon cannot by any chance pass that spot. By the side of this is built a small house, which Mr. Wilmot calls his reception room, and is placed over a small stream, led from the main creek just *above* the breakwater, and passing through the reception room, empties itself in a small but rapid stream into the main creek, just *below* the breakwater. Hence, when salmon come up from the sea seeking for spots on which to deposit their ova, they are stopped by the breakwater, which they vainly attempt to pass. Failing to get farther at that point, they work round the spot until they meet the stream issuing from the house, when, with the natural instincts of their kind, they head up this rapid, and passing through an aperture that affords ingress, but not egress, are safe in the hands of their friend. The water from the auxiliary creek flows into the reception room through two trap doors at one end, and passes out through another at the opposite extremity. Thus the room can be flooded to the depth of four or five feet by shutting the trap door through which the water escapes, and can be shallowed to the depth of a few inches by opening this door and closing the one at the opposite end. Several planks laid partially across the room, edgeways in the water, divide the space into compartments, which enables the breeder to take any salmon out of the water without hunting it about the room or disturbing the other fish. The fish usually come into this reception room during the night, and when thus far up the creek are ready to spawn, and seeking fit places for that purpose. As each new fish arrives in the room, the ova is taken from it at once. The method of doing this is very simple, and does not in any way injure the parent fish. A man goes into the water, and having his hands covered with woollen gloves, to prevent the salmon slipping from his grasp, seizes the fish just above the tail. Two or three platforms cross the room at the height of two feet from the water, and on one of these an assistant stands ready to receive the fish. Wrapping a piece of flannel round it, to counteract its slippery tendencies, he places it between his knees and gently expresses the ova into a tin dish. The salmon is then marked either by a hole stamped through her tail, or by the adipose fin being cut, and turned into the water, having performed the operation for which she had travelled nearly six hundred miles. A male salmon is then caught, and the same process repeated. The melt that is obtained from him is left for a few minutes in the water, until the eggs are impregnated, when they are thoroughly washed and placed on the hatching beds.

Adjoining this is somewhat larger house—sixty feet by twenty—in which the eggs taken from the salmon in the reception room are hatched, and here by these simple means a million salmon can be produced in the year. For while the average per centage of fish raised from a bed of ova in a natural breeding ground is incredibly small, Mr. Wilmot calculates that he can hatch eighty per cent. of the eggs on his stands. It is clear, therefore, that by means of such fish farms as that of Mr. Wilmot, the former abundance of salmon might be restored in a comparatively-speaking short space of time. The artificial hatching of salmon ova in England and America has usually been performed on prepared gravel, and in boxes or in small artificial ponds; but Mr. Wilmot's method possesses a superiority over both these plans, inasmuch as it enables an attendant to remove any addled egg, dirt, or other injurious matter, without disturbing the eggs, at the same time that he can by a glance round the room tell precisely how many eggs are in process of incubation. Down the entire length of the hatching room a sloping stand is built, having a fall of about a foot between end and end; a small stream is led into this house over the upper end of the stand, by means of an underground pipe laid to the creek outside. The stream of water runs into a box at the extremity of the stand, and the overflow from this forms a gentle stream, which courses steadily and evenly down the length of the stand, and falling into another box at the lower end, is carried out into the creek. On this stand the eggs are placed in frames constructed in the form of a schoolboy's slate, but differing from that in having a double set of glass bars in the place of a flat piece of slate. These bars of glass are placed at alternate intervals, so that an egg rests on a bar of the lower set and between two bars of the upper: By this means it is kept immovable in its place, and a frame can be removed from its place to be washed or otherwise dealt with, and replaced without changing the position of a single egg. Each of these frames holds a single layer of one thousand eggs, but the stand is so arranged that three tiers of frames can be laid upon it, each of which will be thoroughly subjected to the action of the stream. Taking a bird's-eye view of the hatching-house, the eggs resemble a bed of pink peas ranged in successive lines, and in this way they remain until the expiration of about one hundred and twenty days, when each will be burst open by the little creature we have before described. As the alien is born, he drops down with the flow of the water, and is taken out of the box at the lower end, and removed to a small strait that leads from the reception house to the creek, at some little distance down. This was cut for a special purpose, which we will explain. At a point a few yards below the breakwater, Mr. Wilmot has commenced to build a dam, and from this point to cut an auxiliary canal to the right of the main creek, which is to carry the rush of water by this new channel into the creek again at some distance from the hatching-house. Between the point where this dam is built and that where the new channel rejoins the original stream, the creek will be quiet and undisturbed by other fish. Into this, then, the small strait runs, so that when young fish appear in the boxes they can be taken out and placed in quiet and secure waters, where they can remain until the time arrives for their seaward migration. Mr. Wilmot has already about two hundred and fifty thousand eggs on his hatching stand, though, as we have said, he has room for more than a million; of these he calculates he will hatch about two hundred thousand fish; and as some few salmon are still coming up, the number of eggs under process of incubation may be considerably increased before the winter sets in. At the same time that this is going on in the houses, the salmon outside in the stream who have not come into the reception room are depositing their spawn in the various gravel beds along the course of the creek, protected from molestation by Mr. Wilmot's jealous care, and unable, because of the breakwater, to get into dangerous localities.

Here, then, is one fish-breeding nursery established by private enterprise, and already laying the foundation of a future supply of salmon. The proprietor of this, with a public spirit worthy of imitation, gives the produce of his labours to the world, for it will be remembered that at the time the fish come to him they are unfit for food, besides being protected by law. Mr. Wilmot has already commenced preparations for further enlarging his breeding ponds; and as year after year goes by, the numbers of salmon will indefinitely multiply, until they of necessity must seek other places in which to breed, and so extend the good work that has been commenced. It is a most interesting occupation, and a most praiseworthy undertaking, and may be beneficially imitated by others who have a little spare time at their disposal, and who are in the vicinity of any stream, however small, that discharges itself into the Lake or the St Lawrence.

By the means of a few such establishments, the former wealth of salmon may be restored, the lake again stocked, and one of the most valuable products of our country be once more within the reach of all.

Moles—Field Mice.

A CORRESPONDENT at Gloucester wishes to know, through the *Plowman*, the best method of ridding his farm of moles. The *Plowman* replies:—

What he wishes to exterminate the moles on his place for we cannot understand. These little animals are entirely insectivorous, and the amount of benefit they do is very great. Probably our Gloucester correspondent has confounded with the moles those little animals called Shrew mice, or field mice. They somewhat resemble in form the short-tailed, thick bodied moles, but are herbivorous in their food, and do great damage to the grain crops through the country. The moles may be distinguished by their very smooth, glossy fur, their long pointed heads (one species, the star-nosed mole, having a fringe at the snout), and their diminutive, almost invisible eyes.

A good trap for catching all small vermin of the farm is made as follows: Dig in the earth, in the orchards, and gardens, at the beginning of cold weather, short trenches four feet wide at the bottom, and three feet wide at the top, and about four feet deep; the ends inclined at the same angle as the sides. The earth walls of these trenches, after becoming frozen, are impassable to mice that have fallen in. We have heard of great numbers being taken in these traps, and altogether they are the most effectual we know.

BIRDS AND THEIR USES.—Baron Von Tschudi, the well-known Swiss naturalist says:—"Without birds successful agriculture is impossible. They annihilate in a few months a greater number of destructive insects than human hands can accomplish in the same number of years. Amongst the most useful birds for this purpose may be classed the swallow, wren, robin-redbreast, sparrow and finch." Tschudi tested a titmouse upon rose bushes of his neighbour, and rid the same in a few hours of innumerable lice. A robin-readbreast killed in the neighborhood 800 flies in an hour. A pair of night swallows destroyed in fifteen minutes an immense swarm of gnats. A pair of wrens flew thirty-six times in an hour with insects in their bills to their nests. He considers the sparrow very important; a pair of them in a single day carry 300 worms or caterpillars to their nests—certainly a good compensation for the few cherries which they pluck from the trees. The generality of small birds carry to their young ones, during the feeding period, nothing but insects, worms, snails, spiders, &c. Sufficient interest should be manifested by all to prevent the discharge of fire arms in the vicinity of orchards, vineyards and flower gardens, as thereby the useful birds become frightened.

Veterinary Department.

Open Synoval Cavities.

THE following is the continuation of the article on this subject commenced in our issue of Oct., 15:

"Anatomy is, under the circumstances, a fair guide. Where numerous structures are involved, a well grounded learning is requisite for accurate judgment; but, as regards the knee of the horse, the spot whence the synovial discharge issues is of all importance. The incision must either be very deep and gaping, all subjacent structures being divided, before the knee-joint can be exposed, or else the wound must affect a very circumscribed place. Each of the tendons, when crossing the joint, is embraced in a synovial sheath. From such information, it will instantly be seen how far more likely a sheath is to be lacerated than the joint is to be punctured.

The single point where the joint could be entered, without severing tendon, lies rather on one side than directly in the centre. The vulnerable spot is, therefore, not exposed to the full force of the blow. To lay bare the joint by an ordinary fall, several parts must be divided. Rarely is an accident witnessed of so fearful an extent. Generally, that which is spoken of as open joint proves to be no more than punctured sheath; the presence of synovia being commonly accepted as the proof. But when the joint is really laid open, the immense flow of synovia—so many sheaths being severed—should at once prove the fact.

The probe must next be used. In the first instance, it should be employed to ascertain whether the fall has left any purse or sac at the inferior part of the joint. All which was enforced respecting the use of a metalic wire to a raw wound must here be observed. The probe had better be altogether discarded than employed with the smallest approach to rudeness.

The suspected sac having been discovered, a large spatula is placed below the knee. A knife with a keen point, but with the edge only sharpened for one-third of its length, is to be used. Upon the cutting point of the knife a piece of beeswax is firmly moulded. The wax answers the purpose of a temporary probe; the blade thus guarded, is cautiously inserted beneath the loose flap of skin. When the bottom of the pouch is reached, a certain amount of resistance will be encountered; through this the knife is driven. The force cuts in twain the wax, and pushes through the integument the blade, which the spatula guides from the leg. This operation should be performed quickly; the hand should simply be carried downward, and then brought upward, when all is concluded; care, however, being taken that the withdrawal of the knife does not injure any part save those it was designed to cut.

Should the horse be nervous, it is advisable to blindfold the animal, and order the groom to hold up the sound leg; the creature can then only rear. When thus disabled, that movement is rendered difficult, and it is proportionably slow. The operation, if properly performed, should be over before action can be prepared for; and by the knife a considerable incision is made in the bottom of the sac, through which all grit or dirt can, with the pus, readily pass.

The examination concludes with a second resort to the probe. The instrument is in surgery of great use; but, as it is commonly employed, reason may doubt whether injured life has been much benefited by its invention. It generally is roked and poked about as though the person holding it was determined, at all hazards, to ascertain the length, breadth, and every irregularity of the wound he is asked to cure; much harm is thereby done. Delicate attachments which, if not interfered with, might induce speedy reunion, are thus broken down, and the injury aggravated; while the operator thinks he ought to know all about the lesion he is to treat, and supposes that he can possibly do no harm with the instrument which the best schools order to be employed.

A good surgeon has no curiosity to gratify; all he desires to know is so much as will enable him to benefit the patient placed under his care. Therefore, never abuse the probe in cases of open synovial cavities. Imagine the distance the bones are from the surface, and, if the probe can enter a very little beyond that distance, such a fact demonstrates the cavity to be exposed. When a horse is before you with synovia running from a wound upon the knee, have the leg lightly flexed; look for the most free space, and into that insert the probe. The bones of the knee-joint are directly under the skin, and when no opposition is encountered for three-quarters of an inch, be certain the joint is exposed.

Most of the cases narrated as opened joints were simple punctures into synovial sheaths; as such, they were sufficiently serious; but not of so important a character as is assumed for them. Synovia is placed between the ends of bones, its use being to prevent the friction which otherwise would be occasioned by the movement of one hard body upon another. Being confined in a circumscribed sac, and incapable of much compression, the liquid performs all the uses which could appertain to the most solid substance. When the fluid which, from its thick appearance and mucuous feel, was formerly termed "*joint oil*," has escaped, the bones grate against each other; inflammation ensues; all neighbouring parts sympathise, and the constitution suffers from intense irritation.

Something of this kind happens when a synovial sheath is punctured. The tendon comes in contact with its investing synovial membrane; but there are reasons why that circumstance is not so serious as when the lubricating fluid is released from the cavity of a joint. Tendons support no weight, and their motion is with the sick almost optional. The bones are the pillars on which the body rests; even while the frame is prostrated, a certain degree of pressure is upon them; for that reason, and also because tendon is more highly organized than cartilage, the first mentioned substance is endowed with the greater renovating energy. An open joint is consequently far more serious than a punctured sheath.

Notwithstanding the serious nature of these accidents, when wrongly treated, few injuries yield more kindly to proper measures than do open joints. However, should the ordinary treatment of caustics and bandages be adopted, the entire limb, before the expiration of a week, will be hot, hard, and tense. The health of the animal will be seriously affected by the continued irritation, and the body will rapidly become emaciated. The foot of the limb will, with evident difficulty, be held from the ground. Should not death interpose (the animal being unable to lie down, and the entire weight being cast upon the sound limb), the foot attached to the healthy member frequently becomes affected with the worse form of incurable laminitis.

Even should no such misfortune as laminitis occur, the after deformity and blemish renders the horse almost worthless. The bones sympathise in the general disease, and a large osseous deposit is engendered to mark the surgical inapitude. When bony growth does not follow, the parts lying immediately over the knee thicken; the skin sloughs, and the integument never being restored, a full knee with a lasting blemish is the consequence.—*Turf, Field and Farm.*

The Dairy.

Feeding Milch Cows.

To the Editor of THE CANADA FARMER:

SIR,—Permit me to tell my experience in feeding milch cows, as I have been a constant reader of the CANADA FARMER since the first of January, and have seen many valuable articles on that and other agricultural subjects. I keep a small dairy of twenty-six cows, and have sent my milk to the factory for the last three seasons. Last June I sowed one acre of corn in drills, eighteen inches apart, and commenced cutting and feeding daily on the last of July. When the rain came on in September, I allowed my cows grass afresh, and I omitted feeding the corn four days, and the result was the milk diminished fifty-two pounds per day. I again commenced feeding them with corn, and in four days they gave their usual quantity of milk. Their milk more than doubly paid for the corn consumed. This is the first I have ever written for the CANADA FARMER. I have derived great benefit from reading its pages. You will hear from me again.

East Durham, P. Q. LYMAN CALL,

AMERICAN DAIRYMEN IN SWITZERLAND.—American enterprise appears to be looking to other continents for new spheres of activity. A company of Americans has located a milk-condensing establishment at Cham, by the lake of Zug, in Switzerland, intended to contribute to English consumption particularly. George H. Page, of Dixon, Illinois, is superintendent of the "Anglo-Swiss Condensed Milk Company." Milk from the Alpine region is celebrated for its richness and flavour. About 400 gallons daily is received from the peasants of the neighbourhood, twelve months, as reported by Baron Liebig, has been churned into excellent butter.

DAIRYING IN THE WEST.—In a report of a recent tour in Wisconsin and Illinois, Mr. X. A. Willard refers, among other interesting particulars, to the progress of factory cheese making in Illinois. He says:—

"One thing is certain, the west has improved in the manufacture of dairy products much more rapidly than at the east. They have the advantage of not being wedded to old notions, but start at once from that which is considered the best practice of our best dairymen, and they spare no pains to introduce improvements whenever a chance for such is offered.

It is for this reason that we think dairying will be a success at the west, wherever the lands are adapted to grazing. In the vicinity of Dunton cheese manufacturers have been secured from New York. The Misses Dwyer, of Herkimer county, are managing two factories, and are making an excellent quality of cheese. Mr. Hawks, the manager of the Dunton factory, is from Oswego county, N. Y., and is making a nice dairy. Mr. Danton drove us over to Gen. Cameron's factory, which is located across the prairie from Dunton, and on the river. Here we found the cheese quite uniform, and of clean, sweet flavour, and so far as we tested, free from that peculiar rankness which shippers complain of in western cheese, and which they say comes from Western grasses and water. We have no doubt the system of cooling and deodorising the milk at the farm, before it is put into the cans to be carted to the factory, will be put in practice generally at the West, and should this system prevail, and New York dairymen continue to cart their milk as at present, without the cooling and deodorising process, then New York must look well to her laurels, for Western cheese will have a reputation for fine flavor which it does not now always obtain."

THE CALVES.—There is no part of the farm stock more liable to be neglected in fall than the calves which have been raised during the summer. They are often left out late in the season, without shelter, to pick at the frozen grass, and by the time cold weather sets in, are reduced in flesh and cannot be wintered without extra nursing, and even then one or more are often lost before the time for turning to grass.

Calves should enter upon cold weather in good condition and with vigorous health. Shelter, and an abundance of nutritious food, should be provided so soon as grass becomes frost-bitten and poor, and cold storms of sleet and rain begin to be frequent. They demand the finest and best hay grown on the farm, and should have in addition a little oil meal, bran or oats. Roots will be found an excellent food for calves during the winter, in addition to the oil meal or bran above mentioned. Some prefer oats, say a pint or a little more per day to each animal. We have seen calves wintered through in fine condition upon hay and oats as above, but we prefer a mixture of oil meal and bran, and if it can be had, a daily feed of turnips or carrots. Calves that are well cared for, that have warm shelter, and that get a sufficiency of nutritious food, not over fed, continue their growth during the winter, and will usually come in milk when two years old, which is a matter of considerable importance to the dairyman. In our experience in raising stock we find by far the most important period to give close attention to the animal is during its first year. Neglect during that time is almost always attended with loss. A poor runty calf, poorly wintered, cannot be expected to be in milk the next year, and at three years old is no better for the pail than the two years old that has had generous treatment and care from its birth—yet the former has cost considerably more than the latter. Many farmers make no estimate of the cost of raising stock, and hence do not properly appreciate the difference between heifers coming in milk when two and three years old. Every animal raised on the farm should be charged with every item of its expense until it begins to pay the farmer back either in milk or beef. By keeping a strict account with stock we are enabled to see at a glance whether there is gain or loss in the business of stock raising. If such accounts were more generally kept, we apprehend more attention would be given to calves in pushing them forward, so that a full and early developement of the animal be secured. Some object to putting calves in stanchions, preferring to let them run loose in the stable. We have never seen any ill effect from stanchioning calves, but, on the contrary, believe there are many advantages from this mode of management.

Less room is occupied when they are thus confined, and they with their stable are kept cleaner than when allowed to run loose. They are more easily fed, especially when any extra food is given, and each one gets its share and is not driven about by master or stronger animals. By giving them a run in the yard every day they get sufficient excercise, while the early breaking to the stanchion, and the handling daily, renders them more docile and more easily managed as they grow older and come in milk.—*Utica Weekly Herald.*

Entomology.

Apple-tree Borers.

In a late number of THE CANADA FARMER—that for Nov. 2, 1868—we published Mr. D. W. Beadle's Prize Essay on "The Apple and its Cultivation," in which the writer gives an excellent account of a borer that affects the apple, its natural history, and the best modes of counteracting its ravages. The insect that he describes is called the Two-striped Borer (*Saperda bivittata*, Say; *candida*, Fab.) from the two chalky-white stripes that run the whole length of the body of the insect, as seen in Fig. 1. The grub that does the mischief is represented in Fig. 2. It belongs to the long-horned family of beetles (*Cerambycidæ*), which includes the majority of our wood-boring insects. It is found in many of the United States, in Lower Canada, and in the Niagara District of this Province; but we have never seen it on the north side of Lake Ontario, nor has it been taken in the neighbourhood of London, Ont. This pleasant immunity, however,—which, alas! may be of no long continuance—is counterbalanced by another Borer of equally destructive habits, to which we now beg to direct the attention of our readers.

Our Borer, like the other, is the larva of a beetle, but of a totally different family; the former has very long antennæ, this one has almost none; the grub

of the former is cylindrical (Fig. 2), that of the latter is flattened, and with the fore-part of the body twice as broad as the rest (Fig. 4.) It is called the Buprestis Borer (*Chrysobothris femorata*, Fab.), from the family of beetles (*Buprestidæ*) to which it belongs. The parent insect is represented in Fig. 3. If the reader will bear these illustrations in mind he will have no difficulty in telling which borer it is that affects his trees, should he be so unfortunate as to be troubled with one or other of the pests, and will know what remedies to apply.

The natural history of the Buprestis Borer may be briefly told as follows:—The egg is deposited by the female beetle in the chinks and crevices of the bark some time during the early part of summer; from this the young grub soon hatches and works his way into the soft sap-wood immediately beneath; here he eats away while the hole inside becomes larger and larger, and he increases in size himself, gradually working his way upwards until he becomes pretty well grown, when he bores into the solid heart of the wood and forms a flattish burrow, corresponding to his own flat form. Some say that this borer never leaves the sap-wood to go into the harder interior, but we have before us a portion of the trunk of a young apple-tree, out of the very heart of which we have cut several of these borers, while others were eating away nearer the surface. When several attack the same tree, their burrows of course approach each other, and sometimes come so near meeting as practically to girdle the tree and cause its speedy death; in any case they very much injure its vitality and bring on decay. We know, indeed, of two young orchards where more than half the trees have been greatly injured by this insect, while some were killed outright; and we have heard of a number of others similarly affected. In the spring of the year, the grub assumes its pupa, or quiescent, state, and comes out as a perfect beetle in the end of June or during July, when it may be found basking on the tree-trunks in the hot sunshine. It is very lively when danger threatens, and will take wing in an instant if an attempt is made to catch it. Its blackish-brown colour above so much resembles the bark of the tree, that it would easily escape the notice of ordinary observers; but beneath it is of a beautifully burnished dark copper colour, looking as if made of metal, and beneath the wing-covers it is bluish-green. The Two-striped Borer attacks the trees as a rule only near the root, though occasionally at the crotch above; the Buprestis Borer is not particular as to his locality, but attacks the whole trunk, and sometimes even the limbs; they both prefer young trees, probably because the bark is thinner and more easily penetrated by the young grub.

The presence of the grub in the tree may be detected by the discoloration of the bark, and its flattened, dried appearance. All such spots should be opened with a knife and the inmate ruthlessly butchered on the spot. In young orchards all the trees should be carefully examined two or three times a year, especially in early spring and fall, and all infected ones be promptly treated with an application of the knife. This, however, is a rather slow and troublesome process; it is much easier to keep off the insect than to kill him when he has effected a lodgement. One mode of doing this is to rub the trees over with common soap—soft-soap will do very well—early in June, just before the beetles begin to lay their eggs, and place also a lump of soap in the crotch of each tree, which will be washed down with the rain. Another mode, suggested by the Rev. R. Burnet of Hamilton, and which, we believe, is likely to prove efficacious—he has tried it himself with advantage—is to plaster over the trunk of the tree with a thick mixture of cow-dung and clay; this is said to prevent the egress of the insect, and cause it to die underneath. We should think that it would also prevent the eggs being laid on the tree, or at any rate be a hindrance to the newly hatched grub in his attempts to penetrate the bark. We have not had an opportunity of testing this method yet, but we propose doing so next season; we trust that some of our readers will also try it, and let us know the result of the experiment. It is only by repeated trials and experiments, by different people, in various localities, that reliable and satisfactory results can be obtained.

The Ravages of Insects.

THE following remarks by N. C. Meeker, from the proceedings of the American Institute Farmers' Club, New York *Tribune*, August 25, 1868, deserve attention:

We may say positively that destructive insects are increasing every year, and that they destroy as great an amount of food as is saved. To meet these scourges will require our best efforts. The science of Entomology, by which insects are classified and their nature studied, is becoming of national importance, and we are sure that without its help little will be done. The first step in every pursuit is analysis, by which we separate a whole into parts, upon each of which attention is to be fixed. Here progress commences. One of the first results in this study is to make distinction between insects which are useful and injurious, for unless this be done one will be as likely to destroy his friends as his enemies. At present this study is so far from being popular, that the greater part of educated men, so-called, are as ignorant as the unlettered. It is manifest that the elements of this science should be taught in our common schools, if it is to become of much use; for the transmission of learning directly from the learned few to the common people, without the intervention of a teacher, is impossible. In fitting teachers for their duties, a knowledge of this science should be included among their qualifications, as much as of arithmetic or grammar. At present, however, we have no colleges where studies of this practical nature are pursued, except incidentally; but when the agricultural universities shall be fairly established, we may expect that the need indicated will be fairly supplied.

Correspondence

A Strange Well.

To the Editor of THE CANADA FARMER:

SIR,—I visited the farm of Robert Henderson the other day, to witness a strange scene. On this land a well has been dug, which is some twenty-two feet deep. From the surface there is a stratum of red clay to the depth of about ten feet, and the rest is tough blue clay, with the exception of about six inches of fine sand, which is perfectly level, with a uniform depth all over the bottom, and out of the sand there is a continual stream of air rushing out in five different places on the East side of the well. Can you, or any of your subscribers, inform me of the cause?

There is no water coming into the well with the exception of some rain water. There was a depth of about eighteen inches some two weeks ago, which was taken out, and the air still kept rushing out with a noise similar to that of escaping steam. There is a depth of five feet of water in it now, which it slashes about with unceasing energy. What is strange, none of the water soaks away, and one side of the well is free from anything of the kind.

If you would answer in your next, you would oblige

WM. HENDERSON.

Blanchard, Nov. 16th, 1867.

NOTE BY ED. C. F.—The cause of the phenomena above described can only be matter of conjecture, in the absence of more complete information of geological surroundings. Air is confined in various cavities below the earth's surface, and not unfrequently subject to considerable pressure. In sinking shafts or wells, an outlet may be afforded, and the imprisoned air escapes with a rush, followed sometimes by water or other fluid. In the case under consideration, the dry stratum of sand has probably a connexion with some reservoir of compressed air, or it may have a sloping course, and somewhere approaches, and perhaps is open to, the surface. This extremity of the porous layer will be the first to receive the rainfall which, as it makes its way downwards, exerts considerable pressure on the air contained in the interstices of the sandy bed. Let alone, the water would gradually make its way downward, and the air escape by the extremity that admitted the water. But an opening having been made in a lower portion of this tube, so to speak, the pressed air finds vent there more readily than through the wet layer of sand above, and is forced out. If this be the case, the escape of air will in time cease, and water will flow into the well from the side whence air now springs. The pressure is evidently on one side only. We do not understand why surface rain water, that has entered the well by its mouth, should not sink through the sand on the side where there is no escape of air, and no pressure from behind. Perhaps it does soak away, but too slowly to have been observed. Perhaps other than surface water has entered. We should like to hear again from our correspondent, and learn the sequel of the curious and interesting case.

Reclaiming Swamp Land.

To the Editor of THE CANADA FARMER:

SIR,—I have a few acres of low land, once thickly covered with tall and handsome tamaracs, balsams, and an occasional cedar and pine. A fire recently swept over this beautiful thicket, burning the trees out by the roots and reducing all the old timber and vegetable mould to ashes. And now the question is, what is best to be done with this swamp?

The soil is *stiff blue clay*. There is no difficulty in drawing off the surface water by means of an open ditch, nor will there be any hardship in making an outlet in case of underdraining. But will it pay to bring such land under cultivation? What is the value of *blue clay* as a soil as compared with clays of other colors? Can this land be made to yield wheat or hay profitably? If so, what previous treatment should it receive?

If you will be so good as to answer these queries in the next issue of your valuable journal, you will very much oblige

AN AMATEUR.

Nov. 17th, 1868.

NOTE BY ED. C. F.—We cannot determine from the above description what is the value of the land in question; but would recommend that it be well drained by ditching in the first place, and sown in grass. It would then, probably, yield good hay. The yield of hay would give evidence of the richness or poverty of the soil, and show whether it would be worth while to incur the expense of underdraining. It would scarcely, however, be adapted for wheat.

Second Agricultural Society of the County of Rimouski, Quebec.

To the Editor of THE CANADA FARMER:

SIR,—As this communication relates to an effort that has been made for the improvement of Agriculture in a part of the Dominion, you may deem it not unworthy of a place in the CANADA FARMER.

Owing to the very large size of this county—the farthest east but one of the Province of Quebec—it was found that only one Agricultural Society was not sufficient for the wants of the inhabitants. Accordingly, a second was formed last March, the bounds of which extend from Métis to Cape Chat, a distance of about sixty miles. The following gentlemen are the present office-bearers:—President, Rev. J. O. Perron, Ste. Felicité; Vice-President, Mr. L. N. Blais, Matane; Sec.-Treas., Mr. A. Fournier, Matane; Directors, Messrs. Alex. Grant, F. Dionne, D. F. de St. Aubin, J. A. Genereux, Ant. Poirier, P. F. Leggat, N. Richard.

Of course, as the Society is of such a tender age, much cannot reasonably be expected from it. Something, however, has been done to accomplish the end for which it is formed. Last summer, prizes were offered for the best farms and best fields of wheat, barley, oats and potatoes. Messrs. Alex. Fraser and X. Imbeau were appointed judges. In the month of August, these gentlemen discharged their duties, and the following is the result:

For cultivated farm, of not less than eighty acres—1st, L. N. Blais, $6; 2nd, F. Dionne, $4.

For land first sowed in 1868—1st, Chas. Truchon, twenty-four acres, $4; 2nd, Rev. J. O. Perron, twenty acres, $2; ; 3rd, Moïse Côté, twelve acres, $1.

For wheat—1st, Oliv. Harrison, four acres, $4; 2nd, Oct. Lepage, six acres, $2; 3rd, Fr. Dionne, three acres, $1.

Barley—L. N. Blais, nine acres, $4.

Oats—1st, L. N. Blais, ten acres, $4; 2nd, Fr. Dionne, do, $2.

Potatoes—Fr. Dionne, —— acres, $4.

Of course the above is not much, but as the Scotch say, "bairns maun creep afore they gang." Arrangements were made for a ploughing match at Matane, in the fall, but for many reasons, into which I need not enter, it did not take place. Next year, the ploughing match is to be at Métis, thirty miles distant. It is to be hoped that the office-bearers will not be again disappointed. An exhibition is appointed to be held at Matane next year. There is to be one every year, alternately, at Matane and Métis.

It is to be hoped that the formation of this Society will prove in the highest degree beneficial to this part of Her Majesty's dominions. To use a very mild phrase, there is in it great room for improvement in agriculture. The views and practices of many of the inhabitants are far behind the age. However, by degrees they will come to see that improvements can be made in agriculture like every other art, and understand the value of agricultural societies. According as they do so the Society will be patronized, and will in turn do the more good.

T. F.

Métis, Q.

Italian Rye Grass.

To the Editor of THE CANADA FARMER:

SIR,—Can you or any of your numerous subscribers give me full information regarding the above grass, if profitable, for this country? What time should it be sown? How much would be an average crop per acre, on sandy land, of a fair tilth? How much should be sown per acre? What is the weight of the seed per bushel? Where can the seed be got, and at what price? How much better is it than Hungarian grass?

J. S. T.

Paris Road, Co. Brant.

ANS.—Italian Rye Grass, which has for some years been extensively used in England, has not hitherto, so far as we are aware, been introduced into this country, and until it has been fairly tested its suitableness for Canadian agriculture can only be a matter of conjecture. We understand it is one of the seeds that Professor Buckland contemplated importing in small quantity, for the purpose of experiment. The best time for sowing would probably be the beginning of May, using from one to two bushels of seed to the acre. The crops in England, on suitable soils, are often very heavy, yielding sometimes as much as three tons to the acre; and two crops are frequently taken in one year. But it requires a naturally rich soil to make any good return, and usually demands, for profitable culture, a large amount of manure. We do not know the standard weight of the seed. It would have to be imported from England, and could most likely be procured through any regular seedsman. It hardly admits of comparison with Hungarian grass, which is an annual. As already stated, actual experiment alone can determine its value in this country.

The Canada Farmer.

TORONTO, CANADA, DECEMBER 1. 1868.

Emigration.

MR. W. FRANK LYNN, a gentleman who takes great interest in the colonies, and has done much to diffuse information about them, and especially about Canada, among the various classes in England likely to emigrate, is at present in this country, endeavouring to obtain from our Government, press, and public men, some practical co-operation in the promotion of his views. His plan is, that the Government authorities here, through the municipal institutions of the country or otherwise, should organize a system, and employ agents in Canada in collecting returns at fortnightly or monthly intervals, respecting the number and class of workmen required, the wages usually paid, and the cost of provisions and living in each principal town and district, together with any other particulars that might be useful; and that this information should be forwarded, as soon as collected, to England, when he would undertake, by means of the press and the connection he possesses amongst the working classes, to have it regularly and properly published in a way that would reach every class of agricultural or artizan workmen.

He is of opinion that the publication of actual statistics, prices current, and tables of wages, would have more effect on working men and middle-class people than any other description of information. The cost of diffusing this kind of intelligence need not be much. Mr. Lynn thinks £500 or £600 a year would suffice; and if the effect of it should be, as he believes, to induce a better and more substantial class of emigrants, the country would soon more than get its outlay back again. He argues that the great hindrance to emigration hither is ignorance of the country, and states that there is not only great ignorance respecting Canada in England, but a large amount of strange and absurd misconception. One intelligent person remarked to him that he supposed tigers and serpents abounded about Toronto, and not a few with whom he has met objected to coming to Canada because they understood the people led a semi-savage life. It is not long since an agent of the British and Foreign Bible Society, addressing a Toronto audience, expressed his astonishment at finding the people so decently dressed; and if an educated man knew no better than to expect to find Canadians only half clad, we need not wonder if persons less well-informed should fall into similarly ludicrous mistakes. Mr. Lynn says it is exceedingly difficult to get people to believe statements respecting the colonies, and that they need to be in some way certified and backed up to gain credence. He tells us that the "Supplement to the CANADA FARMER," of which 20,000 copies were issued some four years since, for circulation in England, and which contained a vast amount of information about life in this country, was extensively regarded as an advertising puff in the interest of the Canada Company, and its testimony to a considerable extent discredited. Hence he urges the publication in English papers—not only in the leading organs of public opinion, but in respectable local journals—of facts and figures duly certified and accredited, so that they may be past dispute. If, however, there be, as it would seem, distrust and suspicion in regard to such information, and a prejudice against Canada in the minds of the people at home, it will be a matter of some difficulty to gain credence for statements in favour of this country, no matter through what channels they may be made. In this state of affairs we see the fruit of that depreciation of the colonies in general, and of Canada in particular, in which a certain class of British politicians have been prone to indulge, and perhaps, too, the influence of that want of patriotic enthusiasm with which we are ourselves to some extent chargeable. Americans at home and abroad always represent the United States as an earthly paradise, and its government as the best under the heavens. Modesty is all very well, but there are times and circumstances when it is needful to blow one's own trumpet a little. Judicious and energetic advertising helps a country as well as a business. If there are means of giving wide publicity to information about Canada in such form as would inspire confidence, by all means let it be done. An outlay of £500 or £600 a year, in doing this, would surely be money well invested, and could hardly fail to bring a profitable return in the transference of capital and population from Britain to our shores.

Our Dominion and Local Governments have this subject before them just now as one of the matters requiring attention. It is pretty manifest that our emigration agency system needs to be remodelled and made of more practical use. If we are to have agents in the old country at all, they should be practical, pushing men, acquainted with Canada, and in love with it, so as to plead its cause and advance its interests with a will. There is great danger of these foreign emigration agencies becoming mere sinecures. We have greater faith in measures of a more indirect character. Let our Government make Canada a good country to live in; let us establish a liberal free grant land system; let us pass a good homestead law; let us develope manufactures, and push on public improvements; let us be economical, thrifty, and prudent in our public expenditure, so as to keep taxation low; and no fear but population will flow to us. In these days of cheap postage, railroads, and electric telegraphs, people will soon get the news of such attractions. Only create an elysium, and multitudes will want to occupy it. "Where the carcase is, there will the eagles be gathered together."

Australian Agrioulture

We are indebted to the *Mark Lane Express* for the following interesting details respecting the present state of Agriculture in the Australian colonies. From an official copy of the agricultural statistics of Victoria for 1867, it appears that although some attention is still given to gold-mining, the exports of gold averaging about £6,000,003, agriculture and sheep-farming occupy now very prominent places in the industry of the colony. The export of wool now reaches 43,000,000 pounds, or more than double what it was at the time of the gold-seeking mania in 1853. The horses in the colony have quadrupled, there are double the number of sheep, and the cattle keep steady in number and quite adequate to the wants of the increased population; the population in the colony having donbled in twelve years.

The occupied land in the colony now amounts to 7,947,455 acres. The area occupied during the last ten years amounts to 5,840,930 acres, or more than three-fourths of the whole extent of land at present under occupation. The average size of holdings is 325 acres; that of the lots usually devoted to farming pursuits, 104 acres. The average area in occupation to each individual in the colony is 11.5 acres. In the last ten years, settlement has progressed in a faster ratio than the population.

The land enclosed amounts to 6,970,106 acres; of this 1,151,228 acres were fenced-in in 1867. The average area cultivated by each holder is 21.7 acres, of which freeholders contributed 70 per cent., and non-freeholders 30 per cent. The average area cultivated by farmers is 25½ acres, and by squatters 52½ acres. Farmers cultivated thirteen per cent. of the land they occupied, and squatters one per cent. of the alienated land attached to their runs. The extent cultivated by each occupier was the greatest in the year 1861, when the average was nearly thirty-one acres; since that period the tendency has been for settlement to outstrip cultivation, so far as the number of occupiers is concerned. Comparing the land in cultivation with the population of the colony, on an average, 100 acres are cultivated to every 109 individuals. Should cultivation advance in the same ratio, in relation to the increase of population, the next returns should show a proportion of not less than an acre under tillage to each head of the population. This proportion has already been exceeded both in New South Wales and South Australia. In the former colony, according to the latest returns, with a population of 431,000, the number of acres placed in cultivation amounted to 451,000, or a fraction over an acre per head; and in South Australia, during the last season, no less than 4.37 acres were placed under tillage to each individual in the community.

The numbers of live stock returned for Victoria are as follow: Horses, 121,381; cattle, 598,968, of which 140,414 were milch cows; 9,833,139 sheep, and 74,708 pigs. In ten years there has been a net increase of 73,549 in the number of horses, of 4,191,591 in the number of sheep, and of 22,481 in the number of pigs, but a falling off of 47,645 in the number of horned cattle. There are nearly fifteen head of stock of all descriptions to each man, woman, and child in the colony, consisting of about one-fifth of a horse, one head of cattle, fourteen sheep, and one-tenth of a pig; and about 111 head to the square mile, namely, one and a-half horses, nearly seven cattle, 102 sheep, and less than one pig.

In all the Australian colonies, including Tasmania and New Zealand, there are upwards of 600,000 horses, nearly 4,000,000 cattle, 38,500,000 sheep, and nearly 400,000 pigs, or more than 43,000,000 head of stock of all descriptions distributed throughout the group. New South Wales still heads the list in thirteen and three-quarter millions; Victoria stands second, 9,628,000; Queensland third, 8,264,000; and New Zealand fourth, 5,297,000. New South Wales and Queensland are still the great grazing colonies, as they own 2,700,000 head of cattle, and Victoria has under 600,000. As a sheep-breeding colony Victoria stands in an equally good position, surpassing Queensland by nearly 2,000,000, but outstripped by the older colony New South Wales, which owns more than eleven and a-half million sheep.

Passing now to an examination of the agricultural resources and production of Victoria, we find that the most important crop cultivated is wheat, which covered 208,588 acres, and produced 4,611,205 bush. The average produce per acre was—wheat 22.3 bush.; oats 30 bushels; barley 30.2 bushels, potatoes 2.7 tons; hay 1.7 tons. Four years ago vines only covered about 2,000 acres in Victoria, less than one-half the extent of ground now devoted to that culture. The vines numbered 8,231,022, more than half of which are in bearing. The grapes gathered last year amounted to 60,659 cwt., of which 43,395 cwt. were made into wine. The cultivation of tobacco is not increasing in Victoria, the acreage having declined from 623 acres in 1864 to 243 acres in 1867.

In all the Australian colonies, including Tasmania and New Zealand, we find that close upon 2,500,000 acres are under tillage. The greatest amount of cultivation (739,714 acres,) and of lands under vines, wheat, and miscellaneous tillage is in South Australia, as is also the largest extent under hay, if New Zealand (which only returns sown grasses and not hay) be excluded. Victoria can boast of the largest extent under oats and potatoes, and New South Wales the largest under cereals, exclusive of oats (chiefly maize,) and under tobacco. The whole acreage under wheat in all the colonies is nearly 1,000,000 acres, whilst vines now cover 13,519 acres. The acreable yield of wheat, oats, and hay is highest in Victoria; New South Wales gives the highest acreable yield of maize and other cereals; the average yield of potatoes and tobacco is highest in Tasmania; and most wine per acre is made in South Australia.

Returns of the machines and implements in use upon farms and stations in Victoria, and of their value, are given: from these, it appears that 165 steam-engines, of an aggregate power equal to that of 1,239 horses are used by farmers, and twenty-two steam-engines of 142 horse-power by squatters. The total value of the plant or machines and implements possessed by farmers amounted to £804,515, whilst that in the possession of squatters is only valued at £61,182. The crops reaped and sown by machinery covered 160,649 acres, of which all but 1,100 acres were upon farms. The number of persons employed upon farms is 42,211, and upon squatting stations 9,640.

There are 114 mills for grinding and dressing grain in the colony; 106 of these are worked by steam and eight by water-power. The amount of horse-power employed is 2,052. There are 355 pairs of stones at work, and the quantity of grain operated on was 4,000,000 bushels. The flour made during the year was 85,586 tons. The approximate value of the machinery and plant of the flour mills was £176,425. There are now 86 breweries in the colony, employing 648 hands and 471 horses. Nearly 9,000,000 gallons of beer are made, and in the manufacture of which 539,000 bushels of malt, 603,289 lbs of hops, and 6,290,000 lbs. of sugar are used.

In closing this summary, it may be added that as there are stated to be officially 43½ million acres of land available for agricultural or pastoral purposes in the colony, and as not eight million are yet occupied, there is ample room for expansion of population and stock, even at the rapid rate at which they have been shown to be increasing.

The "Prairie Farmer on" Reciprocity.

Several influential interests in the United States oppose the renewal of Reciprocity. Foremost among these is the wool interest. As its mouthpiece and advocate, the *Prairie Farmer* says in a recent issue:—

"Various mercantile, shipping and fishing interests are laboring with the powers at Washington for a renewal of the Reciprocity Treaty. There is at least one branch of farm industry that stands fundamentally opposed to this Treaty. This is the wool branch. Since the passage of the present tariff granting protection to the producers of combing wools, an immense amount of capital has been invested in the long-wooled breeds of sheep, such as are universally bred in the Dominion of Canada. This business and capital would suffer immensely if Canadian wools were brought into the States free of duty. It therefore becomes the duty of wool growers, through the Associations, to act in opposition to the effort to include wools in the Reciprocity Treaty. The manufacturers who joined hands with the wool growers in securing the present tariff on wool and woollens, at the meeting of their Association on the 7th of October, gave evidence of their good faith by passing resolutions opposing the movement, on the ground that the advocacy of renewal of the Treaty for the purpose of obtaining Canadian wools free, would be a violation of the spirit of the agreement with the wool growers, upon which the present tariff on wools and woollens was founded, and they say, 'that any advantage which might accrue to the worsted manufacturers from free introduction of combing wools under the proposed Treaty, would be more than counterbalanced by checking the impulse which it has already given to the growth of combing wools here. If the manufacturers oppose the treaty, how much more should wool growers?"

Our contemporary also speaks in terms of high approval of the resolutions against Reciprocity lately passed by the National Wool Growers' Association. All this looks very uncalled-for and absurd, in view of the fact that upwards of nine million pounds of wool have to be imported to meet the wants of American manufacturers, and the other fact, that some seventeen million dollars' worth of woollen goods are brought from abroad to supply the wants of citizens of the United States. When demand and supply are more equally balanced, there will be more consistency in high tariffs and anti-reciprocity.

The Rural New Yorker.—This ably-conducted and popular agricultural journal is to be enlarged to sixteen five-column pages, and otherwise improved on the 1st January next, when it commences its twetieth year and volume.

Editorial Acknowledgement. — Our contemporary, the *Country Gentleman*, in a recent issue, acknowledges the receipt of "a valuable and rare collection of hyacinth and other bulbs," from Mr. James Vick, of Rochester; half-a-bushel of "large and beautiful upland cranberries," from Mr. O. C. Cook, of South Milford, Mass., and "a box of the best honey we have seen in a long time, even better than that received from the same source last year, from Mr. Jasper Hagan, of Albany." Fortunate editor!

Proposed Legislation.—In addition to the Free Grant Question referred to in our last issue, there are other most important measures bearing on agriculture and the rural interests of the Province at present before the Ontario Legislature. In the mining interest very material changes are proposed, especially the abolishing of all royalties and taxes on minerals. A Homestead Exemption Law is also under discussion, which has for its object the exemption of homesteads, to the value of $1,000, from sale or execution for debt. These bills are not yet in a forward state, but by our next issue we hope to be able to report fully and favourably on these important matters. An Act will probably be passed to prevent the setting out of fires during the dry period of the year. Modifications are also contemplated in the sheep and dog law, and a few slight changes in the game law. To these and other kindred subjects that may come before Parliament we will refer again.

Agricultural Intelligence.

Trade with the United States.

EXPORTS FOR THE YEAR ENDING SEPTEMBER 30, 1868.

We subjoin a carefully prepared statement of the principal exports to the United States from this port for the present year, as compared with 1867. Statements of the exports from Port Hope and Cobourg are also given—the three ports being selected as having Consular agencies attached, and forming what has been mapped out by our American friends as "the District of Toronto." As far as it goes, the results shown are complete. It will be observed that this year there have been no exports to the United States in several articles which were largely sent there in 1867; and this is partly accounted for, as far as we can gather, not from any falling off in the exports generally, but from the fact that the traffic in question—with a good deal not here indicated—has sought Canadian rather than American routes of transit. Other markets have probably been found this year, in the varying course of trade, and it is to be hoped that they have all been better. This year

the total exports from Toronto to the States reached about $2,198,279, as against $1,929,588 for the same period of 1867—making an increase in the exports of 1868 of $268,691. This year from Port Hope the total value of the exports to the same quarter is set down at $1,627,169 02; and from Cobourg, $473,376—making the value of the total exports of the three ports foot up to $4,303,824.

Classifying the list of exports in hand, we find it to consist of the following articles:—In grain the total shipments from the three ports reached about 2,434,529 bushels, representing a value of $2,598,955, or within $447,013 of the total exports.

Barley, which, up to the present, has been in most active demand at this point, and which at one time touched the very handsome figure of $1 53 per bush.—constitutes the largest exports in the year's operations; and the figure it commanded this year, as compared with last, was such that though the quantity fell short 1,033,308 bushels, the value represented only shows a decline of $293,425. In 1867, 2,254,463 bushels left this port for the States. This year but 1,221,155 bushels, which are valued at $1,154,300.

Wheat, our next heaviest export, also shows a falling off in quantity and value this year. There were 498,178 bushels sent over, against 872,151 in 1867—showing a falling off in quantity of 373,973 bushels—representing the sum of $609,608.

Of cattle and horses it appears there were exported about 1876, valued at $117,096. Hogs to the number of 470 went the same road, and are set down as being worth nearly $2,000.

As far as Toronto is concerned, this year's business shows a falling off in the lumber sent to the States of 17,841,954 feet, worth in the neighbourhood of $173,000. The total lumber export for the three places, for which these calulations are made, reaches 96,448,107 feet, valued at $1,307,034. The decline in this export, as above noticed, was anticipated this spring, owing to a depression in the business on the other side, and the inability of dealers to hold over stocks till a more favorable period.

The total quantity of wool sent away is set down at 233,058 lbs. for the present year, as against 440,927 in 1867. This evidences a decline in quantity of 207,869 lbs., but the difference in the valuation for the two periods is only $1,722.

In 1867 there were exports in iron ore, rags, oats, hams, pelts, refined oil, safes and shrubbery—none of which appear to have travelled the same road this year. They represent a united value of nearly $93,000. The safes were ten in number, and found their way to our friends in the Lower Provinces, by way of Portland we suppose. Over $40,000 worth of the hams mentioned were sent through to England in bond.

☞ A National Exposition of wools and woollens at New York, in 1869, is proposed.

☞ A Maryland correspondent of the *Country Gentleman* raised 232 bushels of Harrison potatoes from seven and one-half bushels of seed.

☞ A process has recently been patented in England by which the bran of flour, after being separated, is ground into an impalpable powder, and then again mixed with the flour. In this way all the nutritious ingredients are preserved, while the fineness of the flour is not affected.

☞ The experiments made in Chenoa, Illinois, of drying corn by hot air, and thereby getting it to an early market, and obtaining the first prices of the season, are being repaid by a perfect success. Two dry-houses are already in operation, and another is about to be added.

The Berlin *Telegraph* states that upwards of twelve hundred bushels of potatoes, all the way from Riviere du Loup, Province of Quebec, have been sold in Berlin during the last three or four weeks, and readily commanded 70 cents a bushel.

New York State Fair.—The attendance at the N. Y. State Fair, the present year, was 68,000, and yet there were no race-course attractions. Think of this, all New England, and blush at the confession of your exhibition officials, that they cannot make a fair succeed without a horse-trot!

Cattle Disease in England.—A fatal disease has broken out amongst cattle in various parts of England, and has been attributed by many persons to the animal feeding on acorns, of which there has been an extraordinary abundance, while, owing to the long drought, the usual herbage has been extremely scarce. The true cause of the disease is still, however, involved in considerable obscurity.

Apples at the Nova Scotia Provincial Exhibition.

The *Nova Scotia Journal of Agriculture* for October, which has been only lately received, contains a report of the addresses delivered at the opening and closing of the recent exhibition, and a brief report of the apples shown. The latter account is furnished by G. A. S. Crichton, Vice-President of the Fruit Growers' Association. The following is the list of the apples exhibited:—

Doz.		Doz.	
20	Gravensteins.	1	Fall Pippin.
22	Ribston Pippins.	1	Red Astrachan.
24	Baldwins.	2	Gilliflower.
15	Yellow Belle Fleur.	2	Early Bough.
10	Rhode Island Greening.	3	Early Strawberry.
9	Nonpareil.	3	Golden Ball.
5	Blenheim Pippin.	1	Hubbardtown Nonsuch
8	King of the Pippins.	3	Keswick Codlin.
1	York and Lancaster.	2	Monson's Sweet.
15	Pomme de Neize.	2	Porter Apple.
5	Drap d'Or.	1	Yel. Newtown Pippin.
8	Gloria Mondi.	3	Swaar.
10	Emperor Alexander.	1	Sponge Apple.
2	Blue Fermaine.	1	Brabant Belle Fleur.
5	Pomme Grise.	1	Hughes Pl. pin.
5	American Golden Russet.	1	Dressed.
6	Spitzenberg.	1	Early Calkin Pippin.
12	Flushing do	1	Green Newtown do
3	Broadwell.	3	20 oz. Pippin.
12	Northern Spy.	1	Wolfville Beauty.
6	Pound-sweet.	1	Malden's Blush.
3	Sweet Russet.	1	Golden Sweet.
6	Colvert.	1	Bishop Bourne.
3	Canada Reinette.	1	Purple Gilliflower.
7	King of Tomkins Co.	5	Tallman Sweet.
4	Calkins Pippin (Late).	2	Strawberry Permaine.
2	Minister Apple.	2	Dutch Codlin.
3	Roxbury Russet.	2	Early River.
2	Golden Pippin.	2	York Greening.

In reference to the display from Ontario, the writer says: I weighed several varieties with the following results:—

		lbs.	oz.
6	Canada Gravensteins weighed	1	15½
6	N. Scotia do	2	1½
6	Canada Belle Fleur do	2	13
6	N. Scotia do	3	3½
12	Canada Belle Fleur do	3	3
12	N. Scotia do	3	0½
6	Gloria Mundi—called in the Canadian List:—White Spanish Reinette. }	2	13½
6	N. Scotia Gloria Mundi do	2	2½
1	do do	1	0

—circumference, 13 3-8.

Mr. Crichton, however, admits that the Canadian apples, though beaten in point of size by Nova Scotian specimens, were, some of them especially, of very superior flavour, and instances the Gravenstein, Fameuse and Pomme Grise as being in this respect remarkably excellent. We do not know how far our Canadian apples were duly represented.

The Commissioners have resolved to issue, as soon as possible a full Report of the Exhibition, including a revised edition of the Addresses delivered and a complete and carefully corrected List of Prizes and Extra Awards, Lists of Committees, Jurors, &c. The Report will be printed so as to form a convenient permanent Record of the Exhibition.

New System of Rose Culture.

Our foreign Exchanges describe a novel method of growing roses, which is coming into fashion, being found to secure the grand object, namely, great profusion of fine blooms. Its leading points are, *first*, pruning out all the old wood; *secondly*, shortening the new wood very little; and *thirdly*, pegging down the branches flat to the ground. The rose is permitted to bloom only on wood of the previous year's growth, and this young wood is pruned but little. This is quite contrary to all received rules of rose culture, theverthetes, the results are said to be extraordinary. The young shoots, pegged down to the earth, grow very vigorously, and produce abundance of roses at every eye. As fresh shoots put forth from the centre of the plant, those which have yielded flowers are cut away. While it is acknowledged that abundance of flowers can be thus obtained, we observe doubt expressed in some quarters whether as large roses can be got on this system as on the old plan of short and severe pruning. Among other advantages, it is thought the new mode will be favourable to the life of the rose tree, as close pruning is known to be rather exhaustive. The new system was first tried in England and France, two or three years ago, but has more recently been fully tested by a French florist, M. Jean Sisley, of Lyons, who has related his experiments in the *Revue Horticole*. Let our florists try the new method, and see how it answers in the New World. It may have an additional advantage here in securing to the prostrate plants a degree of winter protection, which, in our severe climate, may not come amiss.

The Resurrection Plant.

This is one of the latest curiosities in the plant line. We obtained one of Mr Vick, of Rochester, last spring, and it then resembled a bunch four or five inches in diameter of curled-up shoots of young cedar, with a small cluster of thread-like roots depending from the bottom. Placing it in a saucer of water, the bunch unrolled in a few hours, spreading out quite flat, and presented somewhat the appearance of a heavy patch of moss. In this state it remained two or three weeks. If the supply of moisture failed for a time, the plant gave warning by assuming its regular ball-like form. At the end of that time we transplanted it to the ground, and it looked fine and green under the influence of genial showers. But the weather grew dry, and the Resurrection Plant rolled itself into a ball and rolled away before the wind, the roots not having much grasp on the soil. It lay in the sun on the ground for a month, when we gave it to a friend who placed it in a saucer of water, and lo, it spread out its arms again and showed the green color of vegetable life. An exchange thus speaks of this singular plant:—

"These plants are brought from the southern parts of Mexico. During the rainy season they flourish luxuriantly, but when the dry weather and hot sun scorch the earth, they, too, dry and curl up, and blow about at the mercy of the wind. To all appearances they are as dead as the 'brown and sere leaf,' but as soon as the rain comes again, the roots suck up the water, the leaves unfold and assume a beautiful emerald green appearance. No matter where the plant may be, on a rock, a tree, or a house-top, wherever the winds have blown it, there it rests, and being a true temperance plant, it only asks for water, and at once burs into new life. Having purchased one of these tufts, and placed it in a soup plate filled with water, the reader will be surprised to see it gradually unfold and take on a deep green. The leaves are arranged spirally, and altogether the Resurrection Plant is the latest curiosity."—*Rural New Yorker.*

Protecting Bulbs.

There are many varieties of what are termed hardy bulbs, that will bloom much better than they usually do if protected in winter. A few inches of coarse litter, such as straw, hay, or corn-stalks, will answer the purpose very well; but when these are applied before the ground freezes they help to keep the frost out, consequently mice and ground moles find a very convenient harbor among the bulbs. We have paid pretty dearly for our experience in these matters, and wish that others should profit by our loss. We allow the ground to freeze two or three inches deep before applying the winter protection, and by so doing we do not furnish a retreat for vermin.

When the ground begins to freeze, field-mice look about for a warm location, and if a bed of choice bulbs offers such a place they are pretty sure to find it. It is not the freezing that usually injures half-tender bulbs, but the alternate freezing and thawing; consequently, when the ground once becomes frozen it is an object to keep it so; and there will be but little danger of the bulbs being injured.

We have found that many of the choice varieties of Hyacinths, Tulips, and Narcissus, are often injured in winter if left unprotected, therefore it is an object to cover them if it can be safely done. But where there are ground-mice or field-mice, great care must be given, or these pests will destroy as fast as one can plant.—*Whitlock's Horticultural Recorder.*

Propagating Grape Cuttings.

I make cuttings in the fall of perfectly ripened wood. Bury them six inches deep in any dry ground. In the spring, after the frost is out, spade a trench or trenches two feet wide, and six inches deep; cover the bottom with any cheap or refuse boards. Set up at each side a six inch board, and spread on the bottom some old hay or straw, half or two-thirds rotten, about one inch thick when packed, and make it very wet.

Fill the box with rich earth. Now, with the hand, open across one end a V shaped trench down to the old straw. Press the cuttings against the side of this trench, about two inches apart, with the upper bud at the surface of the ground. With the hand, take the dirt from the front side of this little trench and press it against the cuttings, leaving a similar trench, which fill with cuttings, and continue until the bed is filled. Then mulch with loose hay or straw two or three inches deep, and with a spout or rose sprinkler make the bed pretty moist.

Now the theory is this: the rotten straw in the bottom retains moisture. The boards prevent the surrounding earth from absorbing that moisture; the mulching prevents the moisture from evaporating, and therefore the cuttings remain moist.

My experience is this—95 per cent. of all my grape cuttings treated as above have grown.

There is another item or two in this process worthy of notice; when the plants are to be lifted for the vinery or for sale, first lift out the side boards, then with a shovel or fork, the plants are taken out with roots entire and uninjured, and also that they may be easily watered, and to some purpose in the dry time.—*Exchange.*

Chinese Primroses.

The double-flowered varieties of the Chinese Primrose form a group of considerable extent, as well as one of great beauty and interest. The old double rose-coloured and double white varieties of former days, attractive and useful as they were, are far surpassed by more modern productions. The law of progress has worked out the most cheering results: awitily and certainly have higher forms come forth from the work-shop of Nature to gladden the eyes of the patient worker in this direction. A few flowers, that represent the latest form of the fine varieties, produced by Messrs. Windebank & Kingsbury, of Southampton, were exposed at a recent meeting of the Floral Committee, and were especially remarkable as containing some very fine flaked varieties of considerable beauty. Singular to say, these fine double kinds are all raised from the seed obtained from single flowers. The double blooms do not produce seed as a rule; and even if they did yield seed, and it were to germinate, the plants so raised would simply produce single flowers. This is a curious fact, but Messrs. Windebank & Kingsbury, as well as others, have abundantly proved that it is so. Semi-double flowers will produce seed, but it is necessary that they should be fertilised with the pollen from the single blooms. They rarely, however, if ever, produce really double flowers when so fertilised, and the number of semi-double flowers are always in a minority—the remainder, and consequently larger part, proving single.

To obtain double varieties the raiser fertilises certain fine and striking single flowers with the pollen of other equally fine single blooms, and the desired result is obtained. This is Messrs. Windebank & Kingsbury's *modus operandi*, the exact details and mode of accomplishment are a professional secret they keep to themselves. That they have hit upon some method of fertilisation by which the production of double flowers is rendered certain is evident; and further than this, they at the same time secure a strong and vigorous constitution for the double kinds. Probably the act of fertilising, say a fine red flower, with the pollen of another flower of the same hue, equally fine in character, is the most likely cause of the production of double kinds of that same hue of color; and a similar process would be attended with a like result, if this hypothesis be a correct one, in the case of flowers of other hues of color.—*Gardiners' Chronicle.*

☞ A new grape, called the Golden Champion, is attracting much attention in Great Britain. It has been originated at Daikeith, Scotland. In constitution it is said to be equal to the Black Hamburg, and it sets freely under similar treatment; ripens earlier, and will keep in condition when ripe, as long as that favourite variety. The bunches are large and well shouldered; berries larger than any grape known. The flavor is peculiarly rich

☞ The apple crop in the valley of the Connecticut is now gathering, and proves much larger than anticipated. In Hampshire county the first quality is selling at 50c. a bushel in the orchards. In some of the valley towns the price is from $2 to $3 a barrel.

Ploughing Orchards.—The following experiment by Mr. H. Dayton, of Alden, Erie County, N.Y., is better than a column of theorizing. His orchard of 2½ acres, which had produced very little fruit for a number of years, and most of that wormy, was carefully ploughed less than two inches deep late last fall, and harrowed and cultivated two or three times in the early part of the present season. The result is, he has picked this fall over 450 barrels of fine smooth apples, bringing in about $1,600. The soil was a sandy gravel, and had been in grass about ten years.

New Dwarf Arbor Vitæ.—Mr. A. G. Burgess, of East New York, recently favoured us with the sight of a specimen of his new Dwarf Arbor Vitæ, which he has named Commodore Nutt. It is very dwarf, growing only four to six inches, and is very bushy, branching out close to and even below the ground, rooting at the base of the stems like box. It is perfectly hardy, and so dwarf and compact that it will undoubtedly become one of the most valuable plants for edging, taking the place of box, which is always more or less injured in our climate. We have no doubt it will prove to be a plant greatly wanted. It has only the long linear leaves of the Dwarf Arbor Vitæ, more like the Retinospora, which gives it the appearance of some species of heath.—*Hovey's Mag. of Hort.*

Robbing Gardens.—Not very long ago, the writer was told by an American gentleman, that, residing in the suburbs of a Western city, he had a garden which had cost him years of care and thought, and a great deal of money. The result was a rich reward in choice varieties of fruit and vegetables; but with the growth of the population round him, the robberies of his garden became so frequent as to convert what should have been the harmless and useful pleasure of his old age into a source of the most irritating annoyance. He had therefore to give his wife the option of remaining there where they were and cutting down all the fruit trees, or of selling the place and removing into town. Now against such lawless constraints as that put upon the most innocent, and even useful gratification of taste—upon a man's very mode of life indeed—it would almost seem as if one might justly defend himself, no matter at what risk to the wrong-doers, who, if they do not like the reception prepared for them, can easily and commodiously stay away. So largely injurious is this kind of theft, that we remember Mr. Greely in one of his essays on apple growing, while urging the planting of apple trees, confessed that one great reason of the diminished number of orchards in the New England States, was the frequent and wholesale spoliation which the proprietors had to suffer, so that really an industry of considerable importance was suppressed by sheer dishonesty.—*Montreal Herald.*

Twelve Thousand Acres of Roses.—Mr. Blunt, the British Vice-Consul at Adrianople, in his report to the foreign office this year, gives an account of the rose fields of Adrianople, extending over twelve or fourteen thousand acres, supplying the most important source of wealth in that district. The season for picking the roses is from the latter part of April to the early part of June; and at sunrise the plains look like a vast garden full of life and fragrance, with hundreds of Bulgarian boys and girls gathering the flowers into baskets and sacks, the air impregnated with the delicious scent, and the scene enlivened by songs, dances, and music. It is estimated that the rose districts of Adrianople produced in the season of 1866 about seven hundred thousand miscals of ottar of roses (the miscal being one and a half drachm), the price averaging a little more than three shillings sterling per miscal. If the spring is cool, and there are copious falls of dew and occasional showers, the crops prosper, and an abundant yield of oil is secured. The season in 1866 was so favourable that eight okes of petals (less than twenty-three pounds); and in some cases seven okes, yielded a miscal of oil. If the weather is very hot and dry, it takes double that quantity of petals. The culture of the rose does not entail much trouble and expense. The oil is extracted from the petals by the ordinary process of distillation.

Poultry Yard.

Dark Brahmapootras.

To the Editor of The Canada Farmer:

Sir,—In the Canada Farmer of Nov. 15, I perceive a letter signed H. M. Thomas, in which mention is made of a pair of Brahmapootra fowls, imported by Mrs. Varley, and of which an illustration appeared in your paper, Vol. 5, No. 1. There is also an advertisement from the same person, offering for sale "three pairs dark chickens from the first dark Brahmas imported by Mrs. Varley, Toronto." In reply to both letter and advertisement, I beg to state that the only chickens from those fowls were bred by us, and are in our possession. The history of the pair is simple enough, and is as follows:—

In April last, the hen being engaged in maternal duties, we mated the cock with an inferior hen of the same breed, for exhibition. They were purchased at what we supposed would have been a prohibitory price, and the cock eventually died on Dominion Day. The original hen we still have, and the offspring (which Mr. Thomas vainly imagines he has got for sale) are good representatives of their illustrious parents, some of the cockerels hatched in May weighing over nine pounds, and are magnificently feathered. It will afford us great pleasure to show our fowls to any who are lovers of poultry. We have also a trio from Mr. Boyle, of Wicklow, whose dark Brahmas won eight silver cups, besides many first prizes last year. These, with a cockerel and three pullets, from Mr. Singleton, of Leicestershire, a pair from Mr. Stephens, of Montreal, bred from his Wicklow birds, and a trio of Houdans, are our importations of this year.

In writing this letter, I do not wish by any means to detract from the merit of Mr. Thomas' birds; they may be first-rate, for all I know; but I must correct the statement that they are from "the first dark Brahmas imported by Mrs. Varley," as the only progeny of that pair are still in our own possession

W. VARLEY,
V.S., 1st class, 13th Hussars.

Nov. 19th, 1868.

Note by Ed. C. F.—We are authorised by Mr. Thomas to state that the advertisement referred to should have read "first *prize* dark Brahmas imported," &c., instead of "first dark Brahmas imported." The omission of the word was an inadvertence which he did not discover till he saw the advertisement in print.

Barn-Door Fowl.

The name "barn-door fowl" suggests in itself the mode in which a farmer expects his poultry to pick up a living—literally by eating the grain dropped from the threshing and various other farming operations, and the seeds and insects procured by scratching on the dung-hill, which, besides feeding, causes them to become public benefactors; for the very seeds they eat would, if returned to the land, propagate a rank crop of weeds.

The question now arises, what cross or crosses of pure-bred fowls will produce at once the largest, best-flavored, and healthiest chickens? The one I strongly recommend is that between the Game cock (to be chosen rather for its size and abundant plumage than for its warlike proclivities) and the Gray Dorking hen. It is generally admitted that the Game bird is good for the table; it is also a good sitter and an excellent mother, but it lacks size. This quality the Dorking gives, and the progeny of the two grow to great weight, frequently quite as large as the pure-bred Dorking itself. They lay and sit well, and the mixture of the Game blood gives a better flavor to the chickens. A further cross in the following year will be advantageously made with the Brahma Pootra fowl; and the third year it will be found wise to turn a few young Game cocks into the farm-yard, so that, by continually introducing fresh blood, is avoided that most pernicious habit of breeding in-and-in, to which I have previously alluded. There are many crosses from which good fowls may be obtained, but I do not think any equal to that I have described, viz: between the Game, the Gray Dorking and the Brahma Pootra.

Although for the purpose of obtaining eggs at a season when they are most expensive, it is a wise plan to save each year several pullets for laying, still the eggs to be placed under the sitting hen should be those laid by two-year-old birds, as they will be found not only more certain to contain a chicken, but the chicken will be stronger than any produced from the egg of a pullet. The number of eggs to be placed under a hen varies according to the size of the bird and the season of the year. My impression is, that too many are generally set, and the consequence becomes manifest in the weakliness of the chickens. In no case should there be more than thirteen eggs, however large the bird, and in most cases ten or eleven are quite sufficient; indeed, in very cold weather, nine eggs are enough for the largest bird to cover. The good effect of setting comparatively few eggs is observed in the strength exhibited by the chickens in escaping from the shell, and the fact that they are all hatched at the same time.—*S. M. Saunders, in Country Gentleman.*

The Dutchman's Hen, or Female Perversity.

"If she will, she will—you may depend on't;
And if she won't, she won't—and there's an end on't."

Once with an honest Dutchman walking,
About his troubles he was talking—
The most of which seemed to arise
From friends' and wife's perversities
When he took breath, his pipe to fill,
I ventured to suggest, that wit,
Was oft the cause of human ill;
That life was full of self-denials,
And every man had his own trials.
"'Tis not the will," he quick replied,
"But it's the won't by which I'm tried.
When people will, I'm always glad:
'Tis only when they won't I'm mad!
Contrary folks, like mine old hen,
Who laid a dozen eggs, and then,
Instead of sitting down to hatch,
Runs off into mine garden patch!
I goes and catches her and brings her,
And back on to her nest I flings her;
And then I snaps her on the head,
And tells her: 'Sit there, you old jade!'
But sit she won't, for all I say,
She's up again and runs away.
Then I was mad, as mad as fire,
But once again I thought I'd try her,
So after her I soon makes chase,
And brings her back to the old place,
And then I snaps her a great deal,
And does my best to make her feel
That she must do as she was bid;
But not a bit of it she did.
She was the most contrariest bird
Or which I ever saw or heard.
Before I'd turn my back again,
Was running off, that cursed hen.
Thinks I, I'm now a 'used up' man.
I must adopt some other plan.
I'll fix her now, for if I don't,
My will is conquered by her won't!
So then I goes and gets some blocks,
And with them makes a little box;
And takes some straw, the very best,
And makes the nicest kind of nest;
Then in the nest the eggs I place,
And feel a smile upon my face
As I thinks now at last I've got her,
When in the little box I've set her;
For to this little box I did
Consider I must have a lid,
So that she couldn't get away;
But in it, till she hatched must stay.
And then again, once more I chased her,
And catched, and in the box I placed her.
Again I snaps her on the head,
Until I fear she might be dead;
And then, when I had made her sit down,
Immediately I claps the lid on.
And now, thinks I, I've got her fast,
She'll have to do her work at last.
No longer shall I stand the brunt
Of this old hen's confounded won't!
So I goes in and tells mine folks,
And then I takes mine pipe and smokes,
And walks about and feels so good
That 'wouldn't' yields at length to 'would.'
And as so oft I'd snapped the hen,
I takes some 'schnapps' myself, and then
I thought I'd see how the old critter
Was getting on where I had set her;
The lid the box so nicely fits on
I gently raised—dunder and blitzen!
(Give me more schnapps, and fill the cup!)
There she was sitting—standing up!"

—*Knickerbocker Magazine.*

☞ During the late poultry exhibition in Chicago, sales were made of fowls to the amount of nearly or quite $1,000. Few fowls were sold at less than five dollars each, and a number of trios of chickens were sold at twenty-five dollars.

The Apiary.

Montreal Apicultural Society.

A Society has been formed in Montreal with the above name—the officers are Mr. G. Lomer, Montreal, President; Dr. Webber, Richmond, Q., and Mr. J. Valiquet, St. Hilaire, Q., Vice-Presidents; Mr. S. J. Lyman, Montreal, Secretary.

The objects of the association are to promote attention to bee-keeping. With this view they will hold exhibitions in connection with the horticultural society, at which prizes will be offered for the best constructed hives, wax, and all preparations of wax, honey and preparations of honey, essays on Bee-keeping, &c. Meetings will be held for discussion of subjects connected with bees.

Wintering Bees.

This was the subject of discussion at the first quarterly meeting of the Apicultural Association, held in the room of the Horticultural Society, Mechanics' Hall, on the evening of the 5th November. Mr. Valiquet, of St., Hilaire, V. P., in the chair, and Mr. S. J. Lyman, Secretary. The conversation was carried on by such experienced bee-keepers as Mr. Valiquet, Rev. Mr. Kabler, German minister, of Montreal, and Mr. Higgins, of Coto St. Paul. All agreed that wintering bees was a very important and difficult part of apiculture, and that it was only strong swarms that had any probability of wintering well; indeed that success in bee-keeping in all its departments was dependent on strong stocks, and that bee-keepers paid special attention to this point. Far better have one strong hive (*i. e.*, full of bees) than two weak ones.

For wintering a large number of hives, Mr. Higgins had made a bee-house, with double walls and charcoal between them; but the heat of so many hives together, notwithstanding good means of ventilation, was found to be so great in March, that the bees were all in commotion, and he had to put out the hives nearly a month earlier than he intended, but he did not find that they suffered much by the exposure.

Mr. Valiquet had found the following plan answer well:—He dug a ditch in dry ground, about two feet deep and three feet wide at the top, and as long as the number of hives required. Across this ditch he laid pieces of scantling, and on these he laid two ten-inch boards lengthwise, on which he placed his hives close to each other. Each hive projected a little over the board on each side, and he also opened the super holes for ventilation. He then covered them with boards, in the form of a roof, with chimneys every ten feet, and covered those boards with straw, banking the whole up with the earth taken out of the ditch. The bees had wintered as well, or he thought better in this way than in a cellar, and he had not been troubled by rats or mice, but it was thought that in some places the depredations of these vermin would be a great objection to this method.

Rev. Mr. Kabler thought that a cellar was the best place for wintering bees, and that they should be placed on tables or suspended to the wall, to prevent rats from getting at them. A dark closet would probably do equally well. It had been thought the cellar must be dry, but he believed that a damp cellar or root-house was equally good, though anything putrid or offensive would be injurious. It was, also, generally thought that the temperature should be near the freezing point, but the President of the Society, Mr. Lomer, who could not be at the meeting on account of indisposition, had wintered bees in a part of his cellar that was quite warm, on account of proximity to the furnace which heated his house, and they came out in spring in fine health. It was also generally thought that ventilation was necessary to bees in winter, but in Germany they were shut up close, and here, he believed, they might be treated in the same way. The great thing to avoid in wintering bees was light. The least streak of light would set them in motion, and they would not only consume more honey, but some would escape, if they could, and all that escaped in winter would be lost. If bees were kept cold they had to consume honey to generate heat, which was saved when they were kept comfortably warm. A hive might be safely wintered out-doors with a box or covering of straw over it, but it would require thirty pounds of honey; whereas, in a cellar that was not too cold, ten pounds would suffice. The door of the hive should be closed with wire gauze, and the bees should be disturbed as little as possible.

Mr. Higgins said when the confinement was prolonged there was great danger of the comb being destroyed by the excrements of the bees, and therefore the hives should be allowed to stand out in this climate until severe frost came in December, and be placed out again about the end of March.

A Fine Yield of Honey.—Silas Timmerman, Clockville, N. Y., writes the *Rural New Yorker* that N. N. Belsinger, of that place, received this season from thirty-six stocks of bees thirty-four new swarms and three thousand one hundred and fifty pounds of cap honey. The glass caps were five by six inches. The honey consisted of two thousand eight hundred and fifty pounds of clover, and three hundred of buckwheat. This is Mr. B.'s third season in the bee business, and his stocks are now nearly all Italians.

Good Yield of Honey.—At the recent autumn competition of the Inverness (N. B.) Farmer Society, premiums were offered for the best and second best samples of honey, in tops and hives. Only one sample was shown, but the quality was fine and well worthy of a prize. The honey was taken from a hive swarmed in June last, and weighed as follows:—1st top, 11 lbs.; 2nd top, 7 lbs.; oke, 11 lbs.; total, 29 lbs. The hive is left for a stock; and has of honey 35 lbs., giving a produce of 64 lbs. to the first swarm. The same stock cast a second swarm later in June, and in September the bees were removed from the hive, and put in with the first swarm kept for a stock. The hive contained 40 lbs. of honey, the produce for the season of one stock being therefore 104 lbs. No bees were killed; and the management was in accordance with an essay on bees published by Provost Mackenzie, of Eilcanach.

Poetry.

A River Lyric.

Under my window, day by day,
The beautiful river rolls away:
Rolls from far off woods of pine
Down to the glittering bay;
By frowning crag and fragrant vine,
Onward still to the foaming brine,
To the ocean's kingly sway.

Many a league in rippling glee
The young brook dances; bird and bee
And flowers that lean from the shadowy grass
Hark to its minstrelsy;
And cloud and star, as above they pass,
In its crystal bosom, as in a glass,
Their radiant beauty see.

But the brook hath heard a legend rare,
The winds have warbled it in the air,
Many an echoed voice hath told
Of a world more strangely fair,
Of a world of waters vast and old!
Oh, to reach those depths of pearl and gold,
Well may the brooklet dare!

Now swells the current, deep and wide,
O'er rock and chasm its strength is tried,
Till in broader channels, smooth and free,
The waves majestic glide;
And on they roll right royally,
Till they feel the heart-throb of the sea,
The ebbing and flowing tide.

Beautiful river, roll away!
Thy seaward current no charm can stay.
And thou, too, haste, O river of life!
Through shadows gathering grey;
Flow from meadows with beauty rife,
Down through channels of storm and strife,
To shores of endless day.

Blythe and gay in the early dawn
Life dances forth to meet the morn,
But fast, fast fade the dew and the balm
Of youth's enchantment born:
In this fuller tide, in this deeper calm,
Let me not utter one mournful psalm
Over the brightness gone.

For as day by day I look on thee,
Beautiful river, flowing free,
I feel the swifter rush of the stream
Which onward rolls with me.
And I gather, at times, thro' mist and dream,
An echoed murmur, a breath, a gleam
Of the everlasting sea!

[*Mark Lane Express.*

The Household.

Keeping Out the Cold.

To the Editor of THE CANADA FARMER:

The house we live in is very cold, caused chiefly, I think, by its standing on blocks one foot above the ground.

For the last three years I have been trying to persuade my father to bank it up, but he argues "that it is *impossible* for any cold to come up through a double floor," although water freezes if spilled on the floor even at this season of the year.

My father is a constant reader of your journal, and thinks whatever you advise is about right. Now, Sir, I have taken the liberty of thus trespassing, hoping that you will persuade father to bank up the house and keep us all from freezing this coming winter.

RURAL DISTRICT.

NOTE BY ED. C. F.—It will afford us great pleasure if any word of ours should make one household warm through the coming winter, and the point referred to by our correspondent is one about which we have no doubt. There are more reasons than we have space to give, why, under the circumstances mentioned, the house should be cold. In the first place, the exposed floor is an additional outer wall, always chilled, and keeping the interior cold. Again, it cannot or is not likely to be so tight that air will not come through, and of course the warmth of stoves, &c., causing heated air to ascend and escape by flues or other ventilators, will bring a rush of cold air from beneath A little practical experience may be still more convincing than any theory or philosophy, and we happen to know from personal trial the difference made in a house by leaving the space under the floor open, and closing it in. Our first winter in the climate of North America taught us many useful lessons, and this among the rest. We entered a new house just as winter set in; the dwelling was far from complete, and, among other imperfections, was not walled or banked up to the level of the floor. We shall never forget the experience of that season. Water spilled on the floor froze and remained solid for days together; if the table was washed even with warm water, the surface was instantly coated with a thin sheet of ice. The windows were imperviously crusted with congealed vapour, presenting, in sunlight, most beautiful frost pictures, which, however, we would gladly have exchanged for a little more warmth. In short, the freaks of Jack Frost were so extraordinary and novel as to be really entertaining. But we tired of them, and before next winter shut him out effectually by covering in the basement of the house. The difference must be tried to be realized. We trust our friend, the writer of the above, will have the pleasure of learning the difference this winter.

Desolation Farm-yard.

I never passed Mr. Parish's old place, when a child, without feeling depressed and gloomy. There were not two rods of fence left standing about the house; the old door-steps were broken in, the doors looked as if the first gust of wind would finish them off, a few lank pigs rooted about the front door, and I have an impression that a sorrowful-faced cow was "staked out" about the premises somewhere. We used to call the place "Desolation Farm-yard," and it well merited its name. The people were not drunkards who owned it; they were only "do-less." The poor wife and mother had little health, and I suppose such a shiftless husband had caused her to lose all heart and spirit. Indeed, I think they hardly realized the true condition of things—the changes in the once respectable place had come on so gradually.

I think Solomon must have had such a place in his mind when he penned the lines, "By much slothfulness the building decayeth, and through idleness of the hands the house droppeth through." This was exactly the case in "Desolation Farm-yard." A few handfuls of nails every year, a few days' work with the paint brush and the white-wash bucket, would have kept the place in decent repair, would have helped the family to maintain a respectable place among their neighbors, and would have prevented the children from growing up such wild little Arabs. Children reared in such a home never can maintain a decent self-respect, nor are they likely to be respected by others. No one would think of inviting the daughters out to a pic-nic or a sleighing party, unless some benevolent person did so out of charity. It would require a pretty brave young man to drive up to "that old house" and wait upon Miss Susan into the carriage.

So, too, young Peter Parish would be sure to "get the mitten" if he proposed to see a neighbor's daughter home from singing school. She could not stand the jests of her companions about "that old house," even if she had thought well enough of Peter. The shadow of Desolation Farm-yard would follow them all their lives, unless they wandered off to distant parts where it was never heard of. Even then the mould of its crumbling walls would cling to their hearts and characters forever.

It is a burning wrong to a child to give it such a home in its early years. An air of thrift and tidiness can go along with very deep poverty, and where it is found there is ever a claim to respectability which will not fail to be recognized. As a poor woman once said, "However poor persons may be, they can almost always afford to buy a peck of lime." A peck of lime, judiciously applied as white-wash, can work wonders on the raggedest home.—*Cor. Country Gentleman.*

Economical Vinegar.

In a new country, where the fruit is scarce, it becomes a matter of no small importance that all should be made the most of. We all like good, pure vinegar, and can be sure of it only when it is manufactured from apples. In the fall of the year, those who have apples are paring and drying them for winter use, which is a very commendable thing to do; and a more commendable thing still, is to save the parings and cores for vinegar, and the way to do it is this:—

When you have quite a quantity, put them in a boiler with water enough to cover them, and boil, or rather soak them, several hours. Then strain the juice by pouring it through a clean basket; pour into a cask where there has been vinegar, and leave it to make itself. If you have no such cask, add half a pint of molasses to each gallon of juice, put in a bit of brown paper, and set it where it will warm. A piece of "mother," or vinegar plant, added, will make the process more rapid.—*Western Rural.*

Steaming Potatoes.

THE secret of "steaming" potatoes is very little understood, and rarely carried into full effect, although it is indispensable to the nutritious development of the vegetable. The whole mystery consists in suffering the steam to escape, and at the same time keeping the potatoes hot.

When the cook throws off the water, under the jurisdiction of the cookery-book, what is she to do next? The steam rushes out, and she places the vessel opposite the fire; but, fearful that the potatoes may cool in the meanwhile, she puts on the cover. Thus she undoes one process by the other; for the steam no sooner escapes from the potatoes, than by being confined by the lid, it condenses rapidly, and falls back in water upon the vegetables.

And thus, through the ignorance and obstinacy of our cooks, we are perpetually served with what are familiarly called wet potatoes—a sort of vague excuse which helps to throw the fault against the season, or the gardener, or anything, or anybody, rather than the real culprit. The Irish peasant woman, wholly ignorant of science, but with instinctive sagacity, gets rid of the difficulty by the simplest process imaginable.

Placing the vessel, without the cover, in a slanting direction opposite the fire, so as to hasten the process of steaming by the external heat, she throws a nap-kin over the potatoes, which receives and retains so much of the steam as does not make its escape, while it performs the equally essential office of preserving the heat of the vegetable below.

When potatoes are boiled—the usual mode of dressing in Ireland—it should be recollected that they are deprived of their nutritious qualities by over-boiling. The peasantry are well aware of this, and say that they are "strongest" when the "bone" is left in them, that is, hard boiled. In this condition they require the powerful digestion of the labourer.—*Western Rural.*

Worms in Milk.

WE (*Gloto-worm*) have received the following note from a scientific correspondent relating to the finding of worms in milk:—A lady, in an agony of fear, took to a Brighton chemist a specimen of milk to be examined, declaring that worms, active and red, were to be found in it, and, having used it at the breakfast table, was much disgusted at the discovery. Examination resulted in obtaining from the bulk of the supply several lively specimens of the larva of the common gnat. The dairyman had drawn his supply of water from a tank that, open to air, admitted the insect—and hence the result.

☞ Why is wheat like a baby? Because it is first cradled, then threshed, and then becomes the flour of the family.

☞ To clean cider barrels, the *Scientific American* says, put lime water and a common trace chain into the barrel through the bung-hole, first tying a strong twine to the chain to draw it out with. Shake the barrel about until the chain wears off the mould or pomace, then rinse well with water.

CIDER VINEGAR.—S. J. Woodman, of Chicago, Ill., writes to the New York Farmer's Club, that a barrel or a cask of now sweet cider, buried so as to be well covered with fresh earth, will turn to sharp, clear, delicious vinegar, in three or four weeks, as good as need be.

BOLOGNA SAUSAGES.—In compliance with the request of a correspondent we furnish a receipt for German or Bologna Sausages:—Mix 10 lbs. of Beef and 2½ lbs. or 3 lbs. of fresh fat Pork, chopped fine, 1 ounce of mace, and 1 ounce of cloves. Stuff the whole into calico bags; leave them a day or two, and then put them in a brine barrel for ten days; then smoke them for a few days. Allspice, thyme, and pepper may be added if agreeable.

HOW TO CLEAN RIBBONS.—Wet the ribbon in alcohol and fasten one end of it to something firm; the other in your hand, keeping the ribbon out straight and smooth, rub it with a piece of castile soap until it looks decidedly soapy; then rub hard with a sponge, or, if much soiled, with the back of a knife, keeping the ribbon dripping wet with alcohol. When you have exhausted your patience, and think it must be clean, rinse thoroughly in clean water, fold between cloths and rub it with a hot iron. Don't wring the the ribbon; if you do, you will get creases in it that you cannot smooth out.—*Maryland Farmer.*

NOVEL RAT TRAP.—Place within the reach of rats some coarse oatmeal, mixed to the consistence of thick gruel, in a tub about two feet in depth—the oatmeal to be about two inches in depth. The rat ventures to eat his prepared repast, and then endeavours to make his escape, but to his great surprise he finds his feet fettered and clogged by his newly-found treasure, and is therefore incapacitated from giving the necessary leap. His fate is sealed. He shrieks to bring his friends and relatives to the rescue, who share the same fate. This remedy is simple.—*Mark Lane Express.*

Miscellaneous.

Teaching Agriculture as a Profession.

WE translate the following judicious remarks from the *Journal de l'Instruction Publique:*—

"We have applauded heartily the foundation of various schools of commerce and agriculture which flourish under our eyes, and we rejoice at their continued success. We have too many professional men, too many young men of talent, led astray by the vanity of their relatives, who wish, at any price, to see an advocate, a doctor, or a notary spring from the bosom of the family. It is necessary to endeavour to remedy this evil inherent in the human heart; and we cannot attain that end more surely than in honoring, by raising on the pedestal of a good education, the position of the farmer.

"Agriculture, like Law and Medicine, has become for us a science. The soil must be studied under all its forms, in all its elements. It will be turned and re-turned hereafter, by hands as intelligent as diligent, like the leaves of a good book.

"Everyone feels that the time is past when the soil poured into our heaped-up granaries the exuberance of its riches: on the contrary, it is necessary to do violence to it in order to extract a miserable subsistence. The days are far removed,—very far, alas!

—when they spread the gourons seed on the ashes, yet warm, of the glades of the forest—when the crops were so luxuriant as to conceal under the undulations of their golden ears the fences and the blackened stumps of the grand old pines, which formerly spread their shade over the place occupied by the rich harvest:—where raspberries, cherries, or wild pear trees showed themselves here and there, with their fruits or their red plumes waving amid the white ears of grain. Antiquity has thus represented Ceres, crowning herself with the flowers of the forest.

"This abundance may be re-created, but not as formerly, by the spontaneous production of the soil, but by the violence which will be done to it—by a profound study of its resources, and by rational culture. Let the pupils run, then, to those invaluable schools, where they will acquire a science more precious than a patrimony—the science of preserving, improving, and fertilizing the exhausted womb of the country."

Farming on Shares.

We are afraid that the old negro's experience, as given in the following paragraph, from the Cincinnati *Gazette*, is too general among the Southern blacks.]

An old negro thus relates his experience in farming on shares, which does not seem to have been altogether successful: "Yousee, mas'r, I sede workenest cullud pussen you ebor did see. I goes out early in de morning and nebar comes hum till plum night. Den Mary, my wife, she work all de day and night and a'most keep the chil'ren, so I lay up all my money. After I was sot free I speculate and make lots of money, put um by in de old woman's stocking and hide him in de logs. Ole mas'r he keep a ding-donglin' an' a ding-dongin' at me to come up and farm fo' him; and de ole 'oman, when mas'r speak ob de chil'ren and ole missus, bust out a crying and say she was a goin' anyhow; so I spees I'd better go too. An' ole master and I went down to town, and a lawyer made a contract and read him all ober, an' he sound all right, an' I put my sign on him. Next day I move up an' 'gin do work. I bire all de han's and massa board 'em. Sometimes it rain, and sometimes de han's bo sick; but it goes on all right until do money gum out ob de stockin'.

When the ole 'oman say de money was out ob do stockin' I tole her to fotch him up; and she as you lib it was all gone. Den de ole 'oman cry an' say we break up; but I tell her de crop was fine, and when we gedder um and sell him, we have more money den afore. When I tole ole mas'r de money was out, he say, 'Dat'a all right, Sam, I gum you lots.' Den I and de ole 'oman laff at what a fool she be fo' crying ober de money in de stockin.' After do crop be gedder, massa an' I settle; and, shu as you born I owe massa two hundred dollars. Mas'r say it all right and gum me de statement on a paper. Den I go down to town, an' take along de contract, and do Bureau man read de statement, an' ole massa charge me for de wet wedder, an' de sick han's, an' de board; and dat make more dan do work an' my money. I tole do Bureau dat was not do bargain; but he read de contract, and, afore God, dat contract change since do lawyer read him. Mas'r say I must work next year fo' make up what I owe him, an' I come down heah to see what I do about um. Tell you, it's mighty hard, mas'r, to lose all de money in de stockin', work hard nil year, and den be in debt.—Do regulationers come roun' one night, tlo me up to a tree an' whip me most to death, to make me tell whar de money dey specs I hab; but I tole dem how I spen' um hirin' ban'a an den dey let mo down, an' break up my furnitore, and go off wid de bedclothes. Mary an' de chil'ren's moe' naked, and we'a mighty poor now!" And the old fellow brushed a tear from his eye and stood waiting for the decision of this mighty Bureau man. This old man lived near Lebanon, Ky., and had walked all the way to Lexington to lay his case before the head of the Bureau.—*U. S. Paper.*

Natrel History of the Black Man.

THE Black Man emigrated tew this free and pius kuntry about 200 years formerly, in the lower story of a vessel; he wuz kindly furnished with a free ride, and sum rice and water for vittals.

Immegintely upon his arrival he commenced bizziness, for other folks, on our Eastern coast, and had plenty tew do.

He was very economical in his habits ov clothes, wearing but fu, and those seldom made out of cassimere.

He okasionally changed his lokation, moving into an adjoining State, but in these journeys he was always kindly furnished with a guide, so that there wuz no danger uv his getting lost.

In these trips he seldom took his family with him; they were either allowed to remain a hum, or made excursions in search of work to other States, under the guidanso of experienced guides.

Once in a while the Black Man would stray away to the cold and bitter North, and got cruelly lost.

His guides would mourn for him then, and search for him, but his family soon got reconciled tew the loss.

Everybody sed, where he lived, that he was the happiest critter that had ever bin discovered yet, with nothing tew do but work, and a kind guide tew watch over him awl the time, and mourn for him when he got lost.

But the Black Man is a very phoolish critter.

After 200 years ov this bliss, he grow cross tew his guides, and wouldn't follow the guides, and the konsequentz iz, that the guides have got mad, and I am afrade that the Black Man will have tew take care ov himself now.

He will find it very different from what it was before.

He haz got tew educate his own young ones now, and learn them how tew apel korrektly, one ov the most difficult things in the world; and he has got tew vote, and keep his familee together, and pay when he rides in the street kars.

I am afrade the Black Man haz made a mistako; if he haz, it iz a bad one, for hiz guides never will take him into their hands agin—no, never! They are mad, an don't like the way the Black Man quit them, when they was driv with bizness, and after they had took so much care ov him for so meany years.

I feel sorro for the guides; they alwus seemed tow have a great interest in the Black Man, but they are mad now and I don't know az I blame them much, for Black ingratitude is the poorest kind ov pay.

It perhaps would be well enuff for me to stait, for the bonefit of new beginners, that the Black Man formerly resided in Africa, before he cum here to look for work.—*Josh Billings.*

Horace Greeley's Barn.

THE philosopher of the *New York Tribune* is a farmer as well as an editor, and appears to have very correct views about most agricultural matters.

His ideas about barns and sheltering stock may be gathered from the following description of his barn from his own pen:—

"My barn is a fair success. I placed it on the shelf of my hill, nearest to the upper (east) side of my place, because a barn-yard is a manufactory of fertilizers from materials of lesser weight; and it is easier to draw these down hill than up. I built its walls wholly of stones gathered or blasted from the adjacent slope, to the extent of four or five thousand tons, and laid in a box with a thin mortar of (little) lime and (much) sand, filling all the interstices and binding the whole in a solid mass; till my walls are nearly one solid rock, while the roof is of Vermont slate. I drive into three stories—a basement for manures, a stable for animals, and a story above this for hay, while the grain is pitched into the loft or 'scaffold' above, from whose floor the roof rises steep, to a height of sixteen or eighteen feet. There should have been more windows for light and air; but my barn is convenient, impervious to frost, and I am confident that cattle are wintered in it at a fourth less cost than when they shiver in board shanties, with cracks between the boards that will admit your hand. No part of our rural economy is more wasteful than the habitual exposure of our animals to pelting, chilling storms, and to intense cold. Building with concrete is still a novelty, and was far more so ten years ago, when I built my barn. I could now build better and cheaper, but I am glad that I need not. I calculate that this barn will be abidingly useful long after I shall have been utterly forgotten; and that, had I chosen to have my name lettered on its front, it would have remained there to honor me as a builder long after it had ceased to have any other significance."

A FRIENDLY PASSENGER.—The Haverhill *Publisher* relates that during the Vermont State Fair a conductor on one of the railroads innocently extended his hand to a rustic young lady, expecting she would produce her ticket. To his great surprise Miss Verdancy quickly seized his hand, squeezed it most affectionately, and with that peculiarity of manner that always marks the so-called "capable girl," pronounded the cheerful conundrum of "How's your folks?" adding the remark that "it was nice weather." A stern sense of duty compelled the conductor to undeceive the fair creature and to explain to her that he wasn't a "friend of the family," and that he must see her ticket or the money for the ride. Amid considerable confusion "Jerooshа" produced her papers and allowed the conductor to pass without further inquiry about his "folks."

NEW SERIES
OF
"THE CANADA FARMER."

THE Publishers of THE CANADA FARMER respectfully announce, that in consequence of the new Postal Law coming into operation on 1st January, 1869, a change in the mode of publishing THE CANADA FARMER has been rendered necessary. Heretofore, all Journals devoted to the advancement of Agriculture in Canada have passed through the Post Office free of postage; but the law enacted at Ottawa last session abolishes this privilege, and imposes a tax which, in the case of THE CANADA FARMER, will amount to Twelve Cents *per annum*, or one-eighth of the annual subscription. On the whole circulation of THE CANADA FARMER, this postage tax amounts to $1,680 annually; and it has to be paid—not by each subscriber on delivery of his paper—but by the publishers in advance, when the papers are mailed.

This measure has entirely changed the conditions under which THE CANADA FARMER has been published since its commencement, five years ago. No expense has been spared in maintaining the character of the paper as a first-class Journal. The best Agricultural writers in the Province have regularly contributed to its columns; the original illustrations have been profuse, and in the best style of art; and the paper and typographical execution have been unsurpassed by any other Agricultural Journal. The price of subscription has been maintained at the lowest price at which a semi-monthly Journal was ever offered to the public—and with the view of aiding the operations of County and Township Agricultural Societies, a very large reduction from that low price has been made to Societies. The New Postal Law puts a totally new aspect on the matter, and readers imperative some change adapted to meet the altered circumstances.

The Publishers of THE CANADA FARMER have resolved to meet the difficulty thus presented to them, by putting forth more strenuous exertions than ever before to increase the interest and usefulness of their Journal, and greatly to enlarge its circulation. They have resolved to commence, in January next, a

New Series of The Canada Farmer,

with a number of new and attractive features—and nothing will be left undone to make the coming series still more worthy of support than the past.

The new series of THE CANADA FARMER will be issued monthly; the size of the page will be nearly as heretofore; but each number will contain

FORTY PAGES OF READING MATTER,

instead of sixteen as formerly. And notwithstanding the new Postal-tax, the subscription-price of the new series will remain as before,

☞ONE DOLLAR PER ANNUM☜

Free of Postage—but without any deductions from that rate. The aid of Agriculturists throughout the Dominion is respectfully solicited in obtaining subscriptions for 1869.

Letters will be addressed as heretofore to

THE GLOBE PRINTING CO.,
TORONTO.

ONTARIO
VETERINARY SCHOOL,

Markets.

Toronto Markets.

CANADA "FARMER" Office, Nov. 30th, 1868.

THE market has been very quiet and dull. The demand has been very limited, and there have been only a few lots offering. Wholesale prices have ranged as follows:—

FLOUR AND MEAL.

Flour—No. 1 Superfine, $4 75; Extra, $5 35 to $5 40; Superior, nominal. *Oatmeal*—$6. *Cornmeal*—$4.

GRAIN.

The market has been quiet and unsettled. We quote wholesale prices:—

Wheat—Spring, $1 3 to $1 05. Fall, do., $1 15 to $1 24. *Oats*—50c. to 51c. *Barley*—$1 20 to $1 35. *Peas*—85c. *Rye*—70c. to 75c.

PROVISIONS.

We quote wholesale prices:—

Butter—Dairy tub per lb., 22c. to 24c.; store packed, 18½c. to 21c.; large rolls, 22c. to 23½c. pound rolls, 26c. to 27c.; grease, 8c. to 10c. *Cheese*—(new) in lots, 11c. to 11¾c. *Pork*—Mess, No. 1 per barrel, $23 to $23 50. *Bacon*—Cumberland cut, 10c.; smoked bellies, 12½c. to 14c.; rolls, sugar-cured, spiced and smoked (new), 12c. to 12½c.; unsmoked, 11c. to 11¾c. *Lard*, in crocks, 16c. to 17c.; in kegs, 14c. to 14¾c. *Eggs*—18c. to 20c.; retail, 20c. to 22c.

THE CATTLE MARKET.

Beeves—There is about an average supply of the inferior qualities, and first-class are scarce and command a higher price than recently—selling at $6 50 to $7; 2nd class, $5 to $6; and 3rd class go off on an average of about $4.

Sheep—There is a fair supply still coming in, but the market is no longer quoted as it was for some weeks past, and all offering in lots find a ready sale. First-class range from $4 to $4 50; second-class, $3 to $4; and third-class, $2 50 to $2 75.

Hides and Skins—Hides, green, rough per lb., 6c. to 6½c.; do. cured and inspected, 7½c. to 8½c.; do. dry, 11c. to 13c. Calfskins, green, 10c.; do. cured, 12c.; do. dry, 18c. to 20c. Sheepskins, $1.

Montreal Markets.—Nov. 23.—*Flour*—Superior Extra, $6 50; Extra, $5 75c. to $6 85c.; Fancy, $5 50c. to $5 40c.; Welland Canal Superfine, $5 10c.; Superfine No. 1 Canada Wheat, $5 to $5 25; No. 1 Western Wheat, $5; No. 2 do. $4 60c. to $4 70; Fine, $4 30c. to $4 40c.; Middlings, $4 10c. to $4 15; Pollards, $3 90c. to $4. *Wheat*—Canada Fall, $1 20c.; Spring, $1 15c.; Western, $1 10c. to $1 11c. *Oats*—Per 32 lbs., 50c. to 52c. *Barley*—Per 48 lbs., $1 10c. to $1 20c. *Butter*—Dairy, 21c. to 23½c.; Store-packed, 20c. to 21c. *Cheese*—Factory 10c. to 11c.; Dairy, 9c. to 10c. *Pork*—Mess, $22 50; Thin mess, $20; Prime Mess, $18; Prime, $15.

London Markets, Nov. 24.—White wheat, $1 10 to $1 15; red fall wheat, per bushel, 90c. to 93c.; Spring Wheat, 90c. to 95c.; Barley, $1 10 to $1 25; Peas, 73c. to 75c.; Oats, 44c. to 46c.

Galt, Nov. 24.—Large quantities of turnips are being sold at 12½c. per bushel. Barley sells at from $1 05 to $1 16. Hay from $11 to $12.

Guelph Markets, Nov. 24.—Fall Wheat, per bushel $1 to $1 08. Spring Wheat, $1 03 to $1 05. Oats, per bushel, 50c. to 55c. Peas, per bushel, 80c. to 83c. Barley, per bushel, $1 10 to $1 15. Wool, 26c.

Hamilton, Nov. 24.—Wheat—fall, white, per bushel, $1 20 to $1 25; red winter, $1 05; spring, $1. Oats, per bushel, 56c. Peas, per bushel, 80c. to 85c.

New York Produce Markets, Nov. 24.—Flour—Receipts, 14,000 barrels; sales, [illegible] barrels; [illegible] to 30c. superior State and Western: $5 25c. to [illegible] for common to choice extra State; $8 20c. to $7 75c. for common to choice extra western. *Rye Flour*—Steady, at $6 to $8. *Wheat*—Dull and heavy; receipts, 230,000 bushels; sales, 30,000 bushels, at $1 48c. for No. 2 spring; $1 43 for Nos. 2 and 3 do. mixed. *Rye*—Firm; receipts, 10,700 bush.; sales, 19,000 bush. Western at $1 40c. to $1 43c. *Corn*—Firmer; receipts, 44,000 bushels; sales, 47,000 bushels, at $1 10c. to $1 12c. for unsound, and $1 13c. to $1 13½c. for sound mixed Western. *Barley*—Steady; receipts, 1,800 bushels; sales, 2,000 bushels French at $2 20c. *Oats*—Firmer; receipts, 115,000 bushels; sales, 64,000 bushels, at 71c to 71½c. for Western, chiefly at inside prices. *Pork*—Lower, at $26 50c. to $27 50c. for new mess; $25 50c. to $26 60 for old do. *Lard*—Heavy and lower, at 15c. to 15¾c for steam; 16½c. to 17c. for kettle rendered.

THE CANADA FARMER is printed and published on the 1st and 15th of every month, by the GLOBE PRINTING COMPANY, at their Printing House, 26 and 28 King Street East, Toronto, Ontario, where all communications for the paper must be addressed.

☞ Subscription Price $1 per annum, (POSTAGE FREE,) payable in advance. Bound volumes for 1864, 1865, 1866 and 1867, may be had for $1 30 each. Subscribers may either begin with No. 1 of the present Volume, or with the first No. of any preceding volume. No subscriptions received for less than a year, and all commence with the first number for the respective years.

CLUBS will be furnished at the following rates:—

TEN COPIES for..... NINE DOLLARS.
TWENTY COPIES for..... SIXTEEN DOLLARS.
FORTY COPIES for..... THIRTY DOLLARS.
ONE HUNDRED COPIES for..... SEVENTY DOLLARS.

To Agricultural Societies ordering more than 125 copies, THE FARMER will be sent at SIXTY CENTS.

THE CANADA FARMER presents a first-class medium for agricultural advertisements. Terms of advertising, 20 cents per line space. Twelve lines' space equals one inch. No advertisement taken for less than ten lines' space.

Communications on Agricultural subjects are invited, addressed to "*The Editor of the Canada Farmer*," and all orders for the paper are to be sent to GEORGE BROWN,
Managing Director.

The Field.

Notes on Spring Work.

Owing to the early setting in of hard frost last autumn there has been a smaller breadth of land prepared for spring crop by fall ploughing than is usual, and it will be necessary to begin operations early this year, if the work of preparation for spring sowing is to be well done. It is better to leave land that is in grass or clover untouched, rather than break it up in order to sow with spring grain, unless it can be ploughed the previous fall. If, however, the land must be used for growing grain, and we know it is very common to break up sod for peas or oats, it should be ploughed sufficiently deep to enable the newly turned surface to be worked with a two-horse cultivator, or sharp toothed harrow, to form a tolerably mellow seed bed, previous to sowing. Let the farmer understand that it is not well to try to get in a great breadth of crops in a hasty manner. A few acres well prepared and cultivated will give twice the yield, with only half the labour at harvesting, that could be obtained from a much larger area with indifferent tillage. "What is worth doing at all, is worth doing well," is an old tried maxim that every farmer should remember and be guided by.

PEAS are usually the first crop that can be put into the ground in spring. They do best on sod land that has been broken up the previous fall, and can be cross cultivated in early spring to make a good, yet compact seed bed. This plant derives a large proportion of its food from the atmosphere, rather than the soil, so that it often brings a good crop with careless cultivation, that would prove fatal to other grain. Yet it is a plant that well repays generous treatment, and likes a good mellow seed bed in preference to the hard ungenial one it usually obtains. There are many varieties of this plant differing mainly in the size of the seed, length of haulm, and earliness of maturity. As a general rule, that which comes earliest to maturity will yield the best crop, and we think that too little attention has been paid to this matter hitherto. We imagine that the *Daniel O'Rourke Pea*, a variety of medium length in haulm and size of seed, and one of early maturity, combining great productiveness with richness in quality, a great favourite with market gardeners, would prove a valuable variety for field culture. It is now so extensively grown for market purposes that the seed can be had for about $1 50 per bushel. It ripens in two months from seed sowing. The quantity of seed required per acre depends a good deal upon the size of the pea; of the small field pea, two bushels per acre are usually sufficient if they are all well covered in, while of the larger kinds from 3 to 4 bushels will be necessary. Peas that are grown thickly will give a large yield of haulm, which is nearly equal in value to clover hay, if cut before it is dead ripe and well saved. We believe that if peas were drilled in like wheat, but at a greater distance apart, say every other drill taken out, they would prove a more productive and sure crop than with the ordinary care they now get. It would be no difficult matter for those who have seed drills to try the experiment and report results. We believe that if early ripening varieties of peas were grown they could be removed from the land in time to grow a crop of late turnips, to be fed off to stock on the ground in November, leaving the soil clean and fit for spring wheat or barley the next season. The best way we know of saving peas from the ravages of the pea bug is to feed them to the fattening hogs early in autumn, before the bug begins its work. Pork can be produced at much less cost at that time than if the fattening process is deferred till cold weather, and will bring as good a price from the packers.

SPRING WHEAT is next in order and is sometimes sown before peas, especially on dry well drained soils, where the land has been prepared by a fallow crop the previous season, and can be easily worked as soon as the frost is out. Wheat requires a compact, yet deep seed bed, more so perhaps than any other crop grown on the farm. There are so many contingencies on which this crop depends that it is always a matter of some risk to grow it; of late years the Wheat midge has proved very destructive to spring wheat, especially since the varieties of Fall Wheat grown have been either so early in maturity as to become nearly ripe before the midge fly appears, or have a coating of chaff so thick that it effectually prevents the worm from reaching the kernel until it is too dry to be penetrated.

So far, we have not yet discovered any variety of spring wheat that can be properly called "Midge-proof," although there are some that appear to be partially so, and gave fair returns last year, in a few favoured localities. Spring wheat requires a soil that contains lime and clay in considerable proportion, and well repays good tillage. If drilled in, 1½ bushels of seed per acre is sufficient: broadcast, 2 to 2½ bushels will be required.

BARLEY.—This crop requires extra care in providing a suitable soil, and good friable seed bed, in order to ensure success. It does best in dry loamy soil that has been well prepared the previous year by a fallow or root crop. It does well after a crop of corn, potatoes, or turnips, to which barn-yard manure has been applied, and well incorporated with the soil. The land must be dry, and free from any liability to retain surface water, which has an injurious effect on barley. The usual way among good farmers of preparing the land, is to throw it up with the plough into ridges of about 15 feet wide the previous fall. As soon as the soil is dry in spring, the land is deeply stirred with a two-horse cultivator, and left a few days to get warm from the sun. It is then well harrowed, the seed sown—either with a drill or broadcast—if the latter: it should be harrowed once, and may then be rolled with a rather light roller, though we do not advise it. Barley is a tender plant, and should not be sown till the soil is warm enough to ensure a quick growth after

the season is sufficiently advanced to avoid danger from hard frosts at night. There are three kinds of barley, viz :—Two-rowed or Chevalier, four-rowed, and six-rowed. The first has been but little grown in Canada, though where tried it has given a large yield of extra good quality. It is the favourite kind in Great Britain, and produces the finest and heaviest kind of grain.

The four-rowed is the variety most commonly grown here, having a stiff straw and large plump grain weighing more to the bushel than the six-rowed.

The six-rowed has one decided advantage in view of the present admitted liability of the crop to be attacked by the wheat midge and to suffer from drought, viz :—it ripens ten days earlier than the four-rowed. Three bushels per acre is the usual amount of seed required when sown broadcast.

There is scarcely any crop on which special manures can be tried to so much advantage as barley. Super-phosphate at the rate of 200 lbs. per acre, sown on the land and harrowed in just before, or with the seed, will give it a rapid growth in the early stages and a tendency to early maturity, besides adding considerably to the productiveness of the crop.

Oats will do well on land that is too heavy or too light for wheat or barley. Rich alluvial flats will grow good oats, and can be at the same time seeded down to permanent grass with timothy and red top. Oats are, however, a foul crop, and except on low meadows should not precede grass or clover, but rather be grown on land that is intended to be devoted to a cleaning crop the next year. They can be sown earlier than barley, though often sown too late after the other grain crops have been attended to. We think they do not usually get a heavy enough seeding. 2½ bushels per acre is about the usual practice here. In England 3 to 4 bushels of seed are given. White oats do best on dry soils, black on moist. In Australia nearly all the hay is made from oats sown at the rate of 4 bushels per acre, the crop being cut and cured when the grain is in the milk. One seeding will give three or four successive cuttings of hay in that climate, where there is no frost to kill the roots in the winter season.

Seeding Clover.—There is so much uncertainty nowadays about getting a successful stand for clover, owing to the variable weather in spring, that many farmers become discouraged and have abandoned the practice of having a clover ley as part of the usual rotation in farm crops. The old rule of sowing clover seed on fall wheat before the last snow of spring melts does not work well. The seed germinates too early, and the young plants get killed out by the spring frosts. We prefer to sow clover on barley, as is done in England. The plan adopted is to sow the clover seed immediately after the barley has been harrowed in, and the first rain will cover it to a sufficient depth to ensure germination, while it would fail to grow if covered to half an inch in depth. Where clover is to be sown on fall wheat, it would be well to sow only half the quantity about the middle of April, and the balance twenty days after, sowing the second seeding across the first to secure an even distribution of the seed.

Cultivation and Preparation of Hemp.

We intended to give an editorial on this subject, and wrote to H. G. Joly, Esq., M.P., of Quebec, who has grown the article for the past few years, and takes a great interest in the advancement of Canadian agriculture, for information; and the reply is so good and practical, that we prefer to give it to our readers, in place of our own article on the subject :—

It is necessary that I should begin by stating, for those who may not be acquainted with the fact, that the male, or fecundating flower of the hemp, and the female, or seed-bearing flower, grow upon separate and distinct plants. So that hemp, unlike flax, whose every plant bears seed, is divided between female, or seed-bearing plants, and male plants, which do not bear seed, but are indispensable for the fecundation of the female plant.

I have never read nor heard that it was possible to distinguish the sex of the plant in the seed of hemp; male and female must, therefore, be sown and grown up together. There is nearly an equal quantity of each; if anything, the female slightly predominates. The male ripens about three weeks sooner than the female. It is known to be ripe when its stem and leaves assume a yellowish hue. That colour makes it easily distinguishable from the female, which, at that time, is still perfectly green.

There are no two countries—scarcely two localities in the same country—where hemp is treated identically in the same way; but I think all the various modes of treatment can be safely classified under one or another of the two following heads—the old-fashioned European, or the new-fashioned Kentucky mode.

The choice of the ground, the way to prepare it, the sowing of the seed, and the cultivation between seed time and maturity, are the same in both these modes of treatment, which, in fact, differ but on one point, the harvesting of the crop.

Choice and Preparation of the Ground.

I will quote some good authorities on that subject, whose words will carry much more weight than mine, merely stating that, from experience, I have found them to be perfectly correct :—

Mr. Bradford, of Kentucky, says :—

"The soil for hemp must be a strong, calcareous, deep, warm, loamy, and perfectly dry one, deeply and thoroughly prepared by ploughing and cross-ploughing, according to its previous condition, until a fine state of tilth is produced."

Henry Clay says :—

"The lands which produce hemp best are those which are fresh, or which have lain some time in grass or clover. Manuring is not much practised yet (in Kentucky). Clover is used in lieu of it. Fall or winter ploughing is practised with advantage. It is indispensable in old meadows or old pasture grounds, intended for producing hemp."

Sebastian Delamer says :—

"Hemp gives but a very unsatisfactory return on soils of too sandy or clayey a nature, on shallow soils, on those which are apt to be scorched by the sun, or are unable to receive their due share of atmospheric influence. Fresh broken lands, in the midst of woods and forests, are favourable to its growth."

Sowing the Seed.

We sow hemp, in the District of Quebec, about the first week in May. You can safely sow yours, in Upper Canada, at least a fortnight sooner. Sow it broadcast, about one bushel to the acre (for hemp grown for rope-making, which is the only kind, I think, can be advantageously raised, for the present, in Canada). Harrow before sowing, and harrow and cross-harrow lightly after sowing.

Never sow seed older than the preceding summer's growth, for it is admitted by every one that hemp seed loses its vitality rapidly. The seed must be plump and full, and rather dark in colour. Whitish and greenish seeds are always bad.

Last year I imported seed from Piedmont, north of Italy. It came to an absurd price, but, with proper management, it ought to be got here for four or five dollars a bushel. This year I import Kentucky or Missouri seed (I think it is the same), for which I expect to pay, delivered in Quebec, from three to three dollars and a quarter per bushel. Mr. Wm. Evans, of the Agricultural Warehouse, Montreal, imports all my seed. From experiments made last year, I am, so far, inclined to give the preference to the Missouri seed over the Piedmontese. Some of the plants from the latter are, it is true, much taller than any produced by the former; but the crop yielded by the Missouri seed was a good average length, and much more equal in height and thickness than that from the Piedmontese seed.

There is no cultivation whatever required between seed-time and maturity; the rapid growth of hemp chokes up all weeds; in fact, it weeds itself.

Harvesting.

I have now reached the point at which the European and Kentuckian modes of treating hemp begin to differ from one another—I mean the harvesting—and I will proceed to show in what that difference consists.

In Europe, when the male hemp has become ripe, it is pulled by hand, plant by plant, allowing the female plant to stand, in order that her seed may ripen, which takes about three weeks from the time the male is pulled. After being pulled, the male plants are laid out to *ret*, or, as it is more generally called in the country, to rot, either on the ground, or in water like flax. The same process of retting is followed both in the European and the Kentuckian treatment of hemp. When destined to be retted in water, hemp is put up in bundles, which must not exceed ten inches in diameter or thereabouts, at the thickest part, so that the water may act easily on the centre of the bundle. Five or six days in stagnant water, when the weather is still warm, is generally sufficient. It takes much longer in running water. When the water is cold, owing to the lateness of the season, it is better to ret on the ground. It takes from one month to six weeks to ret on the ground, the time depending completely upon the greater or lesser frequency of rain.

When the bark which contains the fibre can be easily detached from the wood, in long strips uninterrupted, from the root to the top of the plant, the retting is completed. Hemp ought not to be spread upon the field to dry the moment it is taken out of the water, for it is then soft and brittle, and might be injured. The bundles must be put up standing along a fence, a wall, or, if neither be quite convenient to the pond, some light scaffolding erected for the purpose, after slackening the ties, which can be readily done by pushing them up towards the thinner part of the bundles. They are left standing for a day or two, until the water has run out of them. The plants are then fit to spread on the ground in thin layers. When dried on one side, turn them over, and a few hours of sunshine will complete the operation. Do not take them in unless thoroughly dried.

When the seed hardens, the female plants ought to be pulled. It would not do to wait until the seed is quite ripe, because the bags containing it will then burst, and the seed drops on the ground, and is lost. The seed is allowed to ripen for a few days on the field, care being taken to prevent the head of the plant, which contains the seed, from resting on the ground. It must not be beaten out with the flail. It is too soft for that, and would be crushed. The best plan is to bring barrels or boxes to the field, hold the handful of hemp with one hand, the heads of the plant placed inside the barrel or box, and with the other hand, armed with a small stick, beat the heads until the seed drops, after which operation the female plants are retted in the same way as the male plants.

When the seed is extracted, it is taken under shelter, and laid in very thin layers, not more than a couple of inches thick, for it is very apt to heat when not thoroughly dry. It is well to turn it over from time to time. After a month or so, when well dried, the seed is winnowed and put up in bags or barrels.

Such is the European mode of harvesting. Now for the Kentuckian. In Kentucky, Missouri, and other parts of the States, the whole crop of hemp, male and female, is pulled, or more often cut, at one and the same time. The period chosen is about halfway between the maturity of the male and the female plants, say about ten days after the male has ripened. The instrument used for cutting hemp is something like a reaping hook, only the blade is much stronger, nearly straight, with the slightest inward curve, and about twenty inches long; the handle is straight, two feet in length.

If the crop is to be cut with the hemp-knife, the operator is required to cut at once through a width corresponding to the length of the hemp, and as close to the ground as possible, spreading his hemp in his rear, in an even, smooth swath. It is afterwards spread out on a meadow for retting. This is "dew retting."

I think you will agree with me that the Kentucky mode is preferable, for the following reasons :—

1st. Because it does not exhaust the soil, the seed not being allowed to ripen; but if it stands for seed, it is on all hands acknowledged to be an exhausting crop.

2nd. It saves one pulling, both male and female hemp being pulled or cut at once; and that one pulling saved amounts to more than one half the work of harvesting. It speaks to common sense that the first pulling alone, according to the European system, when you must choose and pull the plants one by one, takes more time than a general pulling or cutting of all the plants at the same time; and when they come in Europe to the second pulling, that of the female plants, as they do not stand quite close together (the male plants having been removed), the work does not proceed quite as rapidly, in proportion to the number of plants pulled, as it does in Kentucky.

3rd. When it is intended to ret hemp in water, the warmer the water is the more rapid and perfect is the retting. Now, as the season advances towards autumn, the water cools rapidly. The ten or twelve days during which the female hemp is allowed to stand after the male is pulled, and the time afterwards required for hardening and ripening the seed, and taking it off (which is often protracted to one or two weeks by rain, for the seed cannot be knocked off unless the plant is perfectly dry), may cause a long delay, during which the water often gets too cold for retting the female plant (as happened to me last fall), and then you must ret on the ground, when the colour is not so fine. This applies more particularly to Lower Canada, where the seasons are shorter.

4th. I think the fibre of the female plant is stronger when pulled before the seed is ripe.

The high price of labour on this continent accounts for the new mode of harvesting adopted in America. The Kentucky hemp is quite as strong as the Russian, but its colour is not as clear, owing to its being retted on the ground, and it accordingly compels the rope-maker to employ tar of a lighter colour, which is more expensive than that required for the Russian hemp. Their water in Kentucky is not soft enough for retting hemp.

The Kentuckians sacrifice the seed, but they have found out that the saving in labour both in the pulling, and afterwards in the curing of the seed, more than compensates for the loss of the seed. In other places, where labour is cheaper, it may be otherwise. We have still got a great deal to learn from experience.

For those who will try the European plan (as both plans ought to be fairly tried) and save the seed, I will state that, taken equal weights of flax seed and hemp seed, hemp seed will yield in oil two-thirds of the quantity that flax seed does. This statement, however, must not be looked upon as conclusive. It is merely a personal opinion, based upon the results of one experiment made this last fall at Messrs. Turcotte's oil mill at Beauport. Those gentlemen had never worked hemp seed before. As we gain in experience we may expect more favourable results. But, even calculating upon that, if an acre of hemp yields, say, twelve to fourteen bushels of seed, and I think it will do that if carefully worked, that yield would be an important item, well worth the farmer's consideration, where cheap labour can be obtained. The oil is employed, in Europe, for painting. I got ours tried here by a reliable painter, and it gave much satisfaction. It appears, however, to change the colour of white lead a trifle more than flax oil does, but it is just as good for every other paint. The hemp cake is fed out to cattle with the same results as flax cake.

We have seen that by following the Kentucky mode of harvesting, the seed is sacrificed. In order to procure the seed necessary for the next season's sowing, they lay out a small patch of good land in hills, a couple of feet in diameter, disposed in straight rows, three feet apart each way. They plant seven to eight seeds in the hill. The same rules observed for the cultivation of Indian corn will apply in the after culture of hemp-seed. Those plants, with plenty of room to expand laterally, will throw out, in every direction, branches that get covered with seed. Of course, their fibre is quite worthless, owing to those same branches, but the yield in seed is extraordinary. I took myself, from two plants, about one pint apiece of clean seed. You can form an idea of how small an area of ground would be required in order to yield one bushel of seed.

As to the pecuniary returns from hemp, grown for the fibre, per acre, I must base my calculations upon the price paid our farmers last summer, namely, half a copper a pound for unretted hemp, and one copper for retted, delivered at the mill. One man was paid at the rate of sixty dollars per acre, irrespective of the value of the seed, but

that was the highest. Those who had well selected the land generally ranged between that rate and thirty-five dollars. The drought in our part of the country was extraordinary. The hemp crop suffered very severely from it, as did the flax, so that our success was far from complete. Some farmers, who had sown their hemp in good soil, but such as Sebastian Delamor describes as "apt to be scorched by the sun," were disappointed. Some others, who pitched it carelessly in poor soil, without due preparation, and expected a miracle, were more than disappointed. One must be prepared to meet these checks with patience. However, the general results of last summer's trial, allowing for the great damage done by the unusual drought, which at one time made me fear that all was lost, were of such a nature as to encourage those upon whose help we must mainly depend—the careful, intelligent and enterprising farmers, whose example will tell in the course of time upon the others.

When the male and female plants are pulled separately, the female being kept for seed, the price of half a copper a pound for unretted hemp is not unfair to the manufacturer. Both plants are then brought to him ripe; the sap is dried up; the leaves are gone, and in that state it will not lose more than half its weight in retting, which will bring it to one copper per pound for retted hemp. True, the manufacturer has got the trouble of retting it, but it may be worth his while to have ponds, and ret it in water, which will give him a superior article, the farmer generally retting on the ground. But that same price of half a copper a pound for hemp not retted, when both the male and female plants are pulled at once, is more than the manufacturer ought to pay; for while the male is dry, and worth that price, the female is still green and loaded with leaves, and will lose more than half the weight in retting; there ought to be some deduction in that case, say one-fifth or one-sixth on the whole; if the crop has been cut down with the hemp knife, the deduction ought to be much smaller, if any, because the manufacturer has not then got to pay for the weight of the roots, which is a considerable item. For my part, until the whole business is more practically understood by us, I would prefer it if the farmer were to ret his hemp himself, even on the ground, and deliver it at the mill at the rate of one copper a pound, as some have done. At that rate one acre, well cultivated, ought to yield him about fifty dollars. It would not impoverish the land if both male and female plants are removed at one time, and would prepare it for wheat.

Of course, it is useless to start the growth of hemp on a large scale, where you are not prepared to dress it. In Europe, they dress it by hand. Labour is too expensive here for such a slow process. We must have recourse to machinery, as they do in the States. A hemp mill worked by water, such as I put up at Lotbiniere last fall, given the motive power (water-wheel, steam or other; it appears that in Kentucky they use horse-power, in the absence of water-power) and a shaft on which to hang two pulleys, one for the break and one for the scutchers, will cost from three hundred to three hundred and fifty dollars, at the most.

The whole machinery consists in a six-roller break (Sandford & Mallory's pattern) manufactured by Mr. Wm. Moody, at Terrebonne, near Montreal, and sold by him for $240, and of two scutching pulleys, with five knives on each, (the pulleys made of birch and pine, and the knives of well-seasoned maple or spring steel). Hemp requires much less scutching than flax, I think two scutching pulleys, with five knives each, will be sufficient for the former, where five such pulleys are required for the latter. Put over the machinery a covering, consisting merely of a roof without sides, so that the dust will not trouble the men.

The scutching pulleys, with the knives attached to them, must be raised off the ground a good deal higher than for scutching flax. The shaft of these pulleys ought to be at least four feet from the floor of the mill, the men who scutch standing on stools. The reason is that, if you leave your scutching knives as low as for flax, the ends of the hemp will lie on the ground (it is often eight or nine feet long) where the knives, in their swift revolutions, pick them up. The hemp then gets entangled, and ultimately rolled up round the shaft, and is lost, as I found out to my cost.

The outlay of $300 to $350 for the machinery of a hemp mill, though not very considerable, is more than one would like to incur for the simple experiment of a new thing, especially when undertaken with some doubt as to the final success. But, without incurring any expense, the trial can be made—as I made it before building the hemp mill—either at any flax-dressing mill, or, in the absence of such a convenience, with the common old-fashioned flax-break, worked by hand, so well known to every farmer. If there be a flax-dressing mill at hand, you can make use, for your experiments, of the flax-break, taking care to slacken a little the screws that keep down the upper rollers. Hemp, being thicker than flax, requires more room between the rollers. If your flax-break is not very strong, to avoid injuring it it will be well to cut off the roots of thick hemp before passing it through the break, but you are not obliged to go to that trouble with a regular hemp-break. Once broken, scutch the hemp with your flax scutching knives, on revolving pulleys, taking great care that the long ends do not get entangled; or with a common hand scutching knife. Six pounds of retted hemp, at the rate of one copper a pound, cost the manufacturer five cents, and will produce one pound of clean dressed hemp. The cost, delivered at Quebec, of Russian hemp of the same quality as our Canadian hemp, was, last fall, about 9c. per pound, which I am told is not a very high price in this market. This would leave a margin of four cents a pound for dressing and delivering here; and I think we could give it cheaper than the Russian, hemp requiring much less scutching than flax. It is indispensable that it should be sufficiently retted, whether that be done by soaking in water or exposure to dew.

We are now beginning to dress our stock of hemp at the mill, for Mr. Onslow's rope-walk at Quebec. By the spring, I shall be able to state with more accuracy the cost of dressing hemp, and the yield of retted hemp in dressed hemp. I should not be surprised if, on an average, it took something less than six pounds for one. Some people tell me that they have found it to be five pounds for one. Experience will show.

I earnestly trust that the results of these experiments will be such as to encourage the cultivation of hemp on a large scale, and that it will be found profitable both to the farmer and to the manufacturer, in Canada, as it has been found in so many countries.

Quebec, Feb. 12, 1869. H. G. JOLY.

NOTE BY EDITOR—Mr. Joly is kind enough to say he will send us one bushel Piedmontese hemp seed, and two bushels of Missouri. We will distribute it in small quantities to any of our friends who may be desirous of making a trial of growing hemp in Ontario, in order to introduce the cultivation of this very desirable crop.

Practical Drainage.

BY ALLAN MACDOUGALL, C.E.

I.

The subject of drainage has been so often dwelt upon, that any remarks on it may now seem superfluous; but to a country like this, where so much land lies yet unbroken, and even on many farms fields are often to be found that are useless in early seasons from their wet state, a few practical remarks may be acceptable to those who are anxious to improve their lands, and would wish to make a commencement this spring. The following remarks are intended to show that, little by little, a farmer ought to drain his lands, using his own and sons' labour with that object, and not run into a large scheme that he may not have means to complete, and so be disheartened at an unfinished work, and blame a project the working of which is bad on account of its incompleteness. Let the work of drainage be commenced on a small scale, doing one field only at a time, and as the improved crops show the advantage, and the purse gets longer, larger portions can be done. It is very necessary, to ensure a proper result from the operations carried on, that each field, as it is drained, is thoroughly drained. One or two large drains from the wettest portions of a field, with a few small ones at varying depths, to wet places, do not fulfil the conditions of proper drainage. They answer for the time being, and for a certain distance on each side draw off the water; but the rest of the field is left without any means of being relieved of the superfluous water, and the consequence is an unequal and irregular crop, while the return to the farmer is little or nothing. Let a plan be resolved upon on which operations are to be conducted; fix on a field that from its position affords a good and easy outfall; it may be to a stream, or the field may bound a road where a drain already exists, or some waste land or mill pond may afford a reservoir for the water.

Outfall is the first thing to be looked to, as on this depends the whole success of after operations; it is not necessary that there be a great slope in the land; water, following the laws of gravitation, will always seek the lowest place, and on many fields that look quite level, or only appear to have a slight fall, so long as it is a uniform one, water will be freely discharged.

If it is necessary to lead the water through one or more fields to get an outlet, then the outfall drain should be taken down the sides of the fields it goes through, so as to be useful in draining the fields on both sides. In laying out the lines of the drains, the eye will always be a very good guide, as one can easily see how land slopes, and in small operations there is no great fear of going wrong, and when the trenches or grips are being cut, a little observation will soon show if the water has a fall or is level, so that an intelligent workman can soon learn how to bring up his drains.

The best time for commencing draining operations is when the weather is dry, particularly where the soil is silty, as the workmen's feet in the grips would cause the silt to purge, and fill up the trenches as soon as they were cut; or the silt, not being dry, would get into the drains, and choke them up. The time for putting in drains ought to be regulated by the cropping and other circumstances. A good time would be as soon as spring has completely taken the frost out of the ground, and the land is sufficiently dry to allow operations to be carried on; or they might be put in when the crop has been taken off the land, about the end of August or beginning of September. They ought then to be slightly covered over with earth, and allowed to remain so for a month or six weeks, as thereby the operations will be greatly assisted, and the work of the drains advanced one season. It is a bad plan to cover up drains immediately after they are laid in. By keeping them open, the trenches or grips let the air get into the ground, which it can only do after they have been filled in, when the drain by its working has drawn out the water, which does not take place thoroughly, sometimes, for two or three years. Thus the action of the drain is retarded, and more especially on land that is only being broken in, and the return for the money is longer in coming in.

Seeding to Grass.

If we wished to have good pasture, and intended the land to be broken up by the plough at the end of two years from the time of seeding, we would sow nothing but clover at the rate of twelve to fifteen pounds per acre. We know many will say this is a heavy seeding, and it is about double the amount usually given by the generality of farmers; but it must be remembered that only a liberal seeding will insure success in obtaining a good stand with so uncertain and capricious a plant as clover, when it is sown alone. As soon as the young plants are well up, a dressing of one bushel of dry unleached wood ashes per acre, sown broadcast, will greatly help them to get established in the soil and resist the drought of summer. Some advise sowing plaster, but it is best to be applied the succeeding year, when the clover has got fairly rooted in the soil. Sown on any grain crop, especially barley, which is the best on which to seed down clover, plaster has the effect of retarding the ripening of the grain, and increases only the amount of straw produced.

For a permanent meadow—one that is to be mowed and pastured alternately for a number of years—there is nothing equal to timothy grass. This plant is perfectly hardy, and withstands the severest of our winters without injury, and if sound seed and enough of it is sown, there need be no failure to obtain a good stand of grass, at whatever time it may be sown. It is a question as to the proper amount of seed required per acre of timothy. It lasts for years, growing in stools of bulbs that enlarge and spread from year to year, somewhat after the manner of a potato onion, and should never be too closely cut or pastured down. Owing to the fact that timothy, if too closely seeded, will grow weak and spindling, and that it seldom produces a good crop until the stools have begun to form and spread, it is advantageous to sow clover in the proportion of three-fifths by weight, or some other grass, along with it, to fill up the ground for the first year or two. The clover soon gets winter-killed out; and if not, the timothy, as it spreads over the ground, displaces the clover. Red-top is sometimes sown with timothy, though more generally it springs up spontaneously. We, however, do not like red-top grass, and for hay alone we prefer the timothy only, or with a small admixture of clover. Timothy, although a very nutritious and fattening grass for stock, gives but little aftermath when mown for hay, and therefore, in seeding down land that is required for permanent pasturage, especially for sheep, other grasses must be introduced that will afford a constant succession of herbage throughout the season.

We think the English practice of sowing several kinds of grass seed together might be carried out here to advantage for permanent meadows. So little has been done in that respect here, that it becomes a difficult matter to know what grasses to recommend, with a certainty that they will succeed in our climate, and few farmers are inclined to try the costly experiment of procuring seed from England to test the matter. Probably the best grass we could obtain, as giving a large amount of nutritious herbage during the latter part of summer and through the autumn, is the *Poa pratensis*, known under the names of *Spear Grass*, *Smooth Meadow Grass*, *Green Grass*, and in Kentucky as *Blue Grass*. It is in a measure indigenous to the country, although said to have been introduced from Europe, and springs up spontaneously in old rich meadows. This is the most valuable natural grass of America, and its prevalence in pasturage is a sign of the land being in good heart and well tilled. On poor or badly tilled land it is rarely seen. The seed is very small and light, weighing about four pounds to the bushel, and difficult to obtain in any quantity. The farmers of Kentucky and Pennsylvania find it comes in of itself on land that has been limed and well manured before being seeded down, so they do not try to save the seed of it. It is of very luxuriant growth, forming a thick heavy sward when once it takes possession of the soil, driving out all other grasses, and lasting for many years, spreading out by means of its perennial creeping roots. Where seed can be procured of this grass, a bushel per acre is the quantity sown—generally in the fall on winter wheat, or very early in spring, before the snow melts.

Of the English grasses, the best known here and most used at home is the Orchard Grass, *Dactylis glomerata*. Sown at the rate of one bushel per acre, this is one of the most valued and common of the pasture grasses, not only of Europe, but also of Asia and Africa. It grows rapidly, to a height of three feet, ripens earlier than timothy, and furnishes a rapidly-growing, dense and nutritive aftermath, and resists the effects of drought remarkably well, but should be closely cropped when used as pasture.

Italian Rye Grass, *Lolium Italicum*, is another European grass of value. It requires two bushels per acre, stands drought well, and is adapted to moist clayey soils, where it gives a heavy yield of herbage of good quality.

On the Application of Land Plaster.

Having been interested in the manufacture and practical uses of land plaster for over thirty years, and after studying its effects upon the various crops to which I have applied it from time to time, I am induced, for the benefit of the farming community, to submit the result of my experiments and experience with gypsum, as a top-dressing for clover, roots and barley, to which crops I have applied it with excellent results.

It is also a useful adjunct in barn-yards, stables, pigsties and cesspools, where it ought to be freely and constantly used, to prevent the escape of the ammonia evolved from decaying urine and animal matter.

There is no doubt that its action, when sown as a top-dressing upon growing crops, is wholly atmospheric, that its affinity for the ammonia, with which the common air is highly impregnated, by the gases constantly thrown off from decomposing matter, causes it to attract and fix these floating essences, for the use and benefit of the crops to which gypsum has been so applied; and though it may have no direct affinity for pure water, still I find that green crops, especially clover, which have received a top-dressing of gypsum, in attracting the ammonia during the night, also retain the dew in which it is embodied; for, in walking over a plastered clover field in the morning, I find my feet saturated with water, whereas, in an adjoining unplastered field, they would as surely come out perfectly dry.

My farm was originally a sandy loam. It has decreased in vegetable mould, and become more adhesive by arable culture for the last 35 years, to which latter effect the intermedis to pasturing of sheep has also contributed.

On this soil, 100 lbs. of plaster to the acre is the maximum quantity required, and when applied in excess, no greater effect is produced.

Used on barley, especially in dry seasons, its effects are beneficial; but when mixed

with two barrels of common salt per acre, the combination keeps the soil moist, strengthens the straw, and produces a better and heavier grain.

On turnips and carrots, a mixture of 100 pounds each of plaster and wood ashes, with two barrels of salt to the acre, applied as a top dressing, will greatly improve the crop both in quantity and quality, and will enable the roots to stand a drought such as they were subjected to last year, and keep green and growing all the time.

In the township of Waterloo the German farmers are applying it in the fall, upon their winter wheat, as they inform me, with good effect. I have not as yet tried it myself, but as they have used it more extensively last season, I presume the experiment is satisfactory.

The evaporation and escape of gases from manure heaps, stables, &c., &c., can be prevented by frequent sprinklings of gypsum, which absorbs these subtle elements, and precipitates them into a fixed salt of ammonia (hartshorn) for the use of the crops to which it may be afterwards applied.

The annual loss to farmers by the waste of evaporation is enormous, as the best and most subtle elements of their manure heaps, and urinal washings, are lost from want of proper economy and care, and, like the riches of a spendthrift, are dissipated to the wind for the benefit of others, and to the ultimate ruin of himself. In manure, upon which plaster has been from time to time applied, decomposition is retarded; but its whole strength is retained intact, and afterwards, when turned out in the field, effluvia is hardly perceptible. This proves that gypsum acts on the gases and ammoniacal matter alone, that it is an effective chemical agent in adapting those elements to the use of growing crops, and that it exerts no influence whatever on the soil itself.

T. W. C.,
P'aris.

Liquid Manure.

In Holland, Belgium, and to some extent in England, one of the great elements of success in obtaining heavy and continuous crops of grass, and green forage for soiling milch cows, from the same piece of land for several successive years, is found in the judicious and extensive use of liquid manures, applied to the land by means of water-carts or force-pumps. This liquid manure is not merely such as can be saved in the drainings of the urine from the stables and farmyards, but much of it is obtained by dissolving the solid excrements of animals in tanks constructed for the purpose. The tanks are so situated as to drain the urine from the yards and buildings, and from time to time the solid excrements are added. The whole mass undergoes fermentation, becoming a thick mud, to which water is added and stirred in, to make it thin at the time it is to be applied to the land.

Our farmers have not yet experienced the great benefits to be derived from this mode of using manure, which would be so peculiarly applicable in our hot, dry summers, and we hope at no distant day to see tanks for the purpose of collecting manure for distribution in this manner become a necessary appendage to every well cultivated farm. But, while we think this mode of applying manure to the soil, especially to grass crops, would be highly advantageous, and repay many times over the cost of tanks, water carts, &c., we imagine that the construction of tanks or cisterns in the farm-yard, in order to collect the liquid drainings of the stables, cow byres, and even the rain from the roofs of the farm buildings, in order afterwards to pump out the contents and spread them over the manure heap, at intervals during the dry weather of summer, would prove of signal advantage to the cultivator of the soil. Ordinary farm-yard manure, as made in Canada, contains a large admixture of vegetable matters, such as straw, corkstalks, &c., which, becoming dried up in summer, resist the decomposing powers of the small amount of excrements incorporated with them, so that by the time the farmer wants to haul the manure out on his fallow or plough it in for root crops, he finds the undecomposed vegetable matter greatly in the way of the efficient incorporation of the manure with the soil. Dried up manure heaps are also greatly liable to become fire-fanged, which destroys their value.

In Belgium these manure tanks are usually constructed by bricklayers, at a price proportioned to their capacity—the larger they are the less the price in proportion, the usual size of a tank or cistern being a capacity to hold 33,000 gallons. In Switzerland they make square holes in the ground, and line the sides with brick set in clay mortar. Where the soil is a tenacious clay, and there is no danger of the liquid manure percolating out at the sides or bottom, it is only necessary to construct the tank in such a way as will keep the sides from falling in, either from the effects of the action of frost or the trampling of animals near it. Where the soil is porous, it becomes necessary to make the bottom of stone flags, with the joints cut square, set on a puddling of strong clay. The wall is then to be built from and on this bottom, and hydraulic cement used instead of common mortar.

The cost of a tank containing, say 25 square yards of brickwork, would be about $50.

Harrows and Harrowing.

There are quite a number of patterns of harrows in use, but a really good harrow is yet a desideratum. There should be two classes of harrows used on every farm: a heavy, square-toothed harrow, to drag over newly turned soil and render the surface level, mellow, and at the same time deeply stir the soil; and a lighter and sharper-toothed harrow to cover in seed and break the crust on the surface, after the young plants have got a start.

We believe harrows might be used with more advantage than is usual among farmers, and we think that a round-toothed harrow, so constructed that the teeth may be raised or lowered by means of screws, to suit the depth they are required to penetrate the soil, would be a great advantage. Besides the usual work done by the harrow, it ought to be used more on fall wheat in early spring, to break the crust left by the washing of the fall and spring rains. Also, barley, or other spring grain, would be greatly benefited by a light stirring of the surface soil before the young plants get too high. Potatoes ought to get a light harrowing, lengthwise of the drills, as soon as the tops are through the soil.

But one of the most neglected uses of the harrow is that of scoring the surface of meadows and clover leys in early spring. It is very generally done in England, and has a wonderfully good effect in giving grass an early start. In old meadows, a little fresh grass seed is usually sown after the harrow has scored the surface, and this fresh accession of grass from seed keeps them in constant herbage to better advantage than trusting to a growth of natural and often inferior grasses, to take the place of those that run out through being too closely cropped by stock. To perform the operation of scoring the surface soil either on meadows or other crops, the teeth of the harrow should be slender and sharp, and so set as not to penetrate deeply enough to tear up the soil, and with it the roots of the plants; and we think that a round toothed harrow would be best for this purpose, being of lighter draft, offering less resistance to the soil, and, as it were, being self-cleaning. The work should be well done by harrowing twice, the one across the other.

Raising Early Vegetables.

Few farmers take the trouble to make a hotbed, or understand its management when made; but any one can obtain early plants of choice varieties of tomatoes, squash, cucumber, melon, cauliflower, &c., with little trouble and at small expense, in various ways. The most common is to sow seeds in boxes filled with rich soil that can be kept in a sheltered place exposed to the sun during the day, and in the house at night, to avoid danger from frosts. This plan, however, seldom produces stocky plants, and, besides, many are lost in transplanting, or from too much crowding.

A better plan is to procure a hundred or two of the smallest sized flower-pots, known as thumb-pots among gardeners. They cost $1 per hundred. Make a large shallow box, capable of holding from twenty-five to fifty of these pots, put a little coarse gravel for

drainage at the bottom of each pot, fill it up with rich earth, and plant from one to half a dozen seeds in each. Fill the box with clean horse dung, free from straw, and plunge each pot in it up to its rim. If handles are put on the box, it can be easily carried in at night, and put out in a warm sheltered spot during the day, watering regularly when dry. As soon as the seeds grow, pull all the plants but one out of each pot, leave that to grow and get strong, and when transplanting time comes you have only to have your holes ready, take your pot out, and holding it upside down, with the rim resting on your fingers, and the plant down between them, give a rap or two on the bottom with your other hand, and on lifting the pot, bottom up, the ball of earth in which the plant grows will be left adhering together, and can be put in the ground at once without disturbing the roots, or any risk of loss of the plant from transplanting, and it will do without shading. If properly put away after using, and cared for, these little pots will last many years.

J. M.

Alsike Clover a Permanent Pasture.

Some five years since, I sowed twenty acres of new land with Timothy Clover and Alsike. At that time Alsike Clover was very high priced, and as a natural consequence, only a few pounds were sown on the twenty acre field. The soil was clay loam, the land generally lay low, and wet, being a hemlock swamp. It was, however, well drained by surface ditches, and about 1st June was seeded with the above grass seed, sown with spring wheat on about ten acres, with millet on about five acres, and with carrots on the remaining five acres. The seed took well on all parts, but the growth on that part sown with carrots was monstrous. About one-half of the carrots were smothered. The remainder did pretty well, but about 1st November the Timothy was in many places two feet high, and plenty of it out in flower; yet although so rank a growth of grass had taken place, we harvested several hundred bushels of carrots. However, the carrots as a crop were certainly a failure. But from that hour to this year, the grass has been splendid, and far better on that first sown with carrots than anywhere else in the field. This fact I account for by the grass seed having such firm root and rank growth the first year. But what I particularly wished to call attention to was, that the Alsike Clover is ten times as thick now as it was when first sown. It seeds before Timothy, and possesses the power and inclination to "catch" in sod land, especially if rather low, and damp. In passing over the field each year about June, I notice thousands of young plants springing up everywhere; so much so, that I believe the Alsike will ultimately have all the land to itself.

C.

Experiments with Wheat in 1868.

For some years we have sown some small portion of our garden with various kinds of wheat, and have derived much amusement from watching its growth, and the date and peculiarities of the insect plagues. Last fall we sowed as usual, on the 7th September, eight different kinds of wheat, and up to the 4th of February of this year 1869, the wheat—notwithstanding the inclement season and entire absence of snow all through January—looked remarkably well. Not a blade seemed injured. It is, at the time I am writing, entirely bare of snow, and has been so for several weeks, and the wonder is that it is not injured past recovery. But more strange than this is the fact that some wheat presented to us by a friend, but too late to sow with the rest, is also uninjured, although not sown until the end of October. I examined it yesterday, and found it to consist of single tender blades—far too late sown to stool out in the least. If the general crop of Canada does as well as this unsheltered experiment, we have as yet derived little injury from the want of snow.

From these facts there would seem to be some other reason than frost and thaws to account for the destruction of the wheat crop, by "winter killing," in March, as we usually find the case. We rarely have such a freezing and thawing January as the one just past, to experiment on. If the young blade and that more mature survive the March trial, I will again communicate the result. The wheat in the experiment above mentioned is entirely unsheltered, and quite as much exposed as any wheat in the fields; and moreover, the wheat was harvested from the same piece of land in 1868, which was again at once sowed with wheat, but was well manured. I have long been convinced that wheat does not injure land to any extent by continuous cropping with the same grain, provided it is well manured.

C.

Goodrich and other Potatoes.

To the Editor.

SIR,—I have noticed several communications lately in your paper concerning the Goodrich seedling potatoes. One correspondent writes in the CANADA FARMER that "the Early Goodrich, Harrison, Calico, and Garnet Chili, are the best of all the seedlings originated and disseminated by the late Dr. Goodrich."

I differ from him in opinion with regard to two varieties, namely, the Calico and Garnet Chili. In 1867 I planted the Early Goodrich, Calico, Cuzco, Gleason and Garnet Chili, on the same quality of soil. The Calico did not yield as much as the Gleason, and the Garnet Chili did not yield over half as much. In 1868 I planted Early Goodrich, Gleason, Cuzco, and Garnet Chili, on the same quality of soil. From half an acre planted with Garnet Chili the yield was 97 bushels. From a quarter of an acre of Early Goodrich, 130 bushels. One-eighth of an acre Gleason gave sixty, and one-eighth of an acre Cuzco produced 83 bushels. I plant in drills, each piece of potato 15 to 18 inches apart. One of my employees dug from the production of one piece of the Cuzco twelve potatoes that weighed eleven pounds.

The quality for the table of all the varieties mentioned here is excellent, so much so that I could sell them in Kingston, if I chose to do so, for fifteen cents per bushel above the market price of other potatoes.

I have never had any experience with the Harrison, but clip the following from the Napanee *Express*, Dec. 11, 1868:—

"A Pennsylvania farmer reports to the *Country Gentleman* that the Cuzco, for profit, outstrips any other potato he raises. He gets this year 500 bushels an acre, where the Peachblow goes less than 300 and the Harrison about 200.

FRED. MEMBERY,
Bath, Ontario.

How to Prevent Smut.

Many of our cereal grains are liable to a disease known as smut, which is caused by the growth of a cryptogamous parasite that fastens upon the grain in the ear, just after the bloom is past, and turns the seed into a mass of blackish dust. This parasite is produced from minute spores or seeds, that seem to adhere to the seed grain, and if not destroyed before sowing, will in some strange and unaccountable way reach up to the heads of the grain, and there become developed into activity. In order to prevent this, it becomes necessary to destroy the spores while they adhere to the seed grain. It is well known that salt acts as a destroyer of all fungoid life, so that by steeping seed grain for a short time in strong brine, or sprinkling a mild solution of sulphate of copper over it, the vitality of the spores of smut attached will be effectually destroyed. Brine is always safe to use, while sulphate of copper is dangerous, it being a deadly poison, and a small portion of the grain impregnated with the latter might accidentally get within reach of poultry or pigs, or even by chance get mixed with what is to be made into flour. When brine is used, it is a good plan to spread the grain, after steeping, on the barn floor, and sprinkle over it fine air-slaked lime, stirring all up together till every seed grain gets a coating of the lime. The operation is to be performed a day or two before the seed is to be sown. We have always adopted this plan with the seed of both fall and spring wheat, and found it greatly diminish, if not entirely prevent, any liability to smut.

Since trees have been planted in Egypt they are beginning to have rain. Plant trees—not trees and fruit trees—they'll pay for their room and care in beauty, shade and fruit. Plant trees.

Duration of Vitality in Seeds.

There are few plants, the seeds of which will not grow in the second year after maturity, if kept in a cool place, neither too dry nor yet too damp. The seeds of most of the grains and grasses will keep their vitality for very many years. Instances have occurred of wheat having been grown from seed supposed to have been buried 2,000 years.

Parsnip and onion seed can only be depended on to grow the year after it matures. Beans are safe only for two years, as also are carrot, egg plant, and several of the pot-herbs. Radish, lettuce, spinach, parsley and asparagus, are good for three years. Celery, cabbage, cauliflower and turnip seed, may be tolerably relied on for four years after maturity. Beet, mangels, tomato, squash, pumpkin, cucumber, and melon, are good for five to ten years, and the four last, which are bi-sexual, generally produce the largest proportion of female blossoms, and consequently fruit, when grown from seed that has been kept from three to six years.

White and Grey Plaster.

To the Editor.

SIR,—In the February number of the CANADA FARMER you have an article on Plaster, of which the following is an extract:—

"It is found in workable quantities in two localities in Ontario, namely, Paris and York, both situated on the banks of the Grand River.

"The whitest plaster is the best, and to be pure it must be beautifully white and semi-transparent.

"The dark colour of the York or Grey plaster is owing to its being impure.

"The grey York plaster is the lowest in price, &c., &c."

In the above you have made a mistake, which please correct in your next issue.

The *grey* plaster comes from Paris, and the *white* plaster from York. We have *no grey plaster in the York beds.*

At the International Exhibition, London, England, 1862, specimens were received from different parts of the world, and those from Canada were sent from the several plaster beds at the expense of the Geological Survey. There was only one first-class prize medal given for plaster on that occasion, and *it was awarded to me.*

ALEXANDER TAYLOR,
Manufacturer and wholesale dealer in plaster, from his beds of pure white gypsum,
York, Grand River, Ontario.
Caledonia, Feb. 23, 1869.

SAVE THE MANURE.—Farmers are not aware how much is wasted on their farms, that with little care and trouble might be made into valuable manure. Everything that can be decomposed, either in process of time, with the assistance of the elements, or by the aid of chemical agents, should be saved for the compost heap. Select some place in the barnyard, or adjacent lot where it will be convenient of access, and there gather your compost, adding from time to time such solvents as may be necessary. Here bring all the weeds, sods, briars, thistles, &c., that you are compelled to dig and cut up through the summer, and add to these from time to time whatever you have of waste material, muck from the swamp, decayed fruits, potato vines, leaves, the deposit from the sink, &c., and at the close of the year you will be surprised at the size of your heap, and be able to see for yourselves how much is really wasted on your farms that might be turned to valuable account.—*Rural American.*

OATS.—To judge by the talk in the American agricultural papers about Norway oats, Surprise oats, &c., and the big yields claimed by those who have the article for sale, the oat fever bids fair to outrival the potato fever. If any of our cousins across the line want a big thing in oats, let them send to Australia for seed. There they can obtain oats weighing fifty pounds per bushel, and giving sixty, eighty, and even one hundred bushels per acre, with the most ordinary care in culture, or almost no culture at all.

EXPERIMENT WITH SALT.—A correspondent in the county of Huron writes some of the results of his experiments with salt as a fertilizer. He tried it on fall and spring wheat in 1868, at the rate of one barrel to the acre. The time of sowing was the 18th of April, and it was sown on ridges in different parts of the field. The result on fall wheat was imperceptible. The spring wheat was treated at the same rate and same time of application. It was sown immediately after harrowing in the wheat. The result on spring wheat was "worse than useless." He gives as a reason that the salt brought the ridges, on which it was sown, forward of the rest, so that the midge ate every bit of it, and concludes with the advice to "experiment with caution."

FIELD PEAS.—Peas will be extensively grown this year, in view of the demand for the article from the States, and the prospect that pork will command a price at which it will pay to fatten hogs. In answer to enquiries as to what variety is best to sow, we can hardly tell; so much depends on circumstances and seasons, that it becomes difficult to recommend one variety over another. Among the newer varieties of field peas lately introduced, the "Crown Pea" holds a high rank for quality and productiveness. The "Golden Vine" is a good variety for rather light soils. For a later ripening variety the "Black-eyed Marrowfat" is growing into favour. The Crown Pea has been extensively grown of late years in the county of Oxford, and a farmer near Ingersoll writes that "they are larger than the common pea, command a higher price, and will yield a third more. They are especially suited to rich strong soils, as they do not run to straw and lie down. They can be cut like hay. I cut mine with a mowing machine. The straw is much liked by stock, and they ripen earlier than most other kinds. I have grown them for the last four or five years, sowing at the rate of three bushels of seed per acre." The price of seed of the Crown Pea is $1 per bushel, delivered at Ingersoll station. Bags or barrels 30c. to 40c. each extra.

BEAVER MEADOWS.—A correspondent, G. W. P., at Bathurst, desires information as to how to treat a beaver meadow that has been cut for forty years, and is now run out. Although we have seen many of these alluvial deposits, and had one on a farm of our own, we cut the natural grass without attempting to improve it. If any of our readers have had experience in breaking up and seeding a beaver meadow with cultivated grasses, we should be glad of the information as to how it can best be done. We think if the soil was dry enough—and if it is not, it might be made so by proper drainage—the natural grass could be turned under with the plough, and the land sown with oats, on which timothy and Kentucky blue grass might be seeded down. If the meadow is wet and mucky, and cannot be drained to advantage, it would be throwing away labour to try to grow cultivated grasses on it; the value of the muck upon it to use in manufacturing manure by composting in the barnyard, stables, &c., would be its chief advantage. Probably filling up the break in the old beaver dam, and thus flooding the meadow for a year or two, would kill out the grass in it, and when the water was let off after the operation, a new and strong growth of blue joint grass (*Calamagrostis Canadensis,*) which is one of our best and most common wet meadow grasses, would take possession of the soil as soon as it became tolerably dry on the surface.

WOOD ASHES AS A FERTILIZER.—This is one of the most valuable fertilizers within the reach of the farmer. The unleached article has the more potash, but the leached is thought to be quite as valuable. In leaching they shrink a good deal, and lime is usually added, which increases their value. They are generally sold, too, at a less price. Ashes are well suited to all farm crops, and are very beneficial in the fruityard and orchard. Most farmers sell wood in the cities and villages, and rather than go home empty they should carry back ashes and other fertilizers, to replace the potash, lime and phosphoric acid that have been carried off in the crops and animals sold. Ashes show immediate effects from their application, and at the same time last long in the soil. They are very highly appreciated in the onion growing districts, but may be applied with equal advantage to ordinary farm crops. They should be kept as near the surface as possible, spread and harrowed into the seed bed or applied directly to the growing crops. Make a business of saving, buying and storing ashes during the winter for the next season's operations.—*American Agriculturist.*

Rural Architecture.

Roofing Materials for the Farm.

NO. 2.

In a previous article under this head we gave some account of Tiles as a permanent roof covering. We now proceed to mention matters of a more temporary nature.

The Celt, in his native place (where, from some reason or another, which it is not the province of this journal to discuss, he seems obliged to resort to all sorts of shifts), is one of the most primitive of roof builders. Rough poles must, of course, be had for rafters, and these are joined without much symmetry; various matters, such as brush, sticks, and other things of temporary growth, form the material to cross the rafters, the whole being covered with turf sods, which in the moist climate grow more or less together, and form a rude means, though not always effectual, of turning off the water. So far does growth proceed in this way, that Walter Scott, in some of his works, points out the roof of the cabin of this construction as giving promise of better pasture than a great deal of the surrounding land. Turf and sods, however, as a class of covering, will, we think and hope, never become a national material in Canada.

The first covering to our settlers' houses is, nevertheless, very little better, and certainly not more lasting, being often formed of basswood troughs, split out of small trees, the round side remaining in its natural state, the flat or split side slightly hollowed with the axe, so as to form a continuous channel for the water. These are made of a length equal to the entire breadth of the building they are intended to cover. They are ranged side by side, the round side down, until the surface is covered. Other logs, similarly split and hollowed out, are prepared, and are made to cover the interstices of the bottom troughs. The vacant spaces are stuffed with moss to keep out the wind. The upper or reversed troughs conduct the water to the under ones, and they carry it free of the building. The troughs form rafter and covering in one, and for the time are a most serviceable roof. Being such as the settler himself can make, there is no outlay, and they do not require a single nail in the whole roof. These troughs are, for shanties, or buildings with only one slope to the roof, very popular in the bush, and are constantly used on the first settlement of new land; but they are not lasting, and seldom remain water-tight for more than five or six years, if so long.

The next Canadian materials are sheets of elm bark; but these are also perishable, and have the double disadvantage of requiring a roof frame to support them. Such as they are, however, they are extensively used in all very new settlements.

Shingles invariably follow in the wake of these expedients; but shingles require lumber or boards on which to lay them, and nails with which to fasten them, all which are serious considerations. The getting of shingles, then, is a question which involves a good deal of thought as well as of exertion.

There is one kind of shingles, called clap-boards, which are free from these objections. They are made of oak, and split into lengths far greater than ordinary shingles. They are then laid side by side, lapping one another and breaking joint, and held in their places by a framework placed across them; loaded in some cases with stones of sufficient weight to keep them all in their places; but these may be considered rather a variety than a different species of the shingle roof.

Good pine shingles, well chosen, split thick, and carefully laid on, have been known to last forty years. Twenty years, however, is the general extreme duration of this roof; they wash away, rather than either rot or decay.

The great English, and indeed European succedaneum for the other kind of roof coverings is "thatch," and it is difficult to find a farm homestead in England, Scotland, or Ireland, without a specimen of this covering. In Canada, however, we must greatly improve in our agriculture before we can adopt the usual thatch of wheaten straw as an ordinary cover for buildings. Straw thatch denotes a superabundance of the article of straw; and here, unfortunately, we have universally a deficiency of that substance. Still, under most circumstances, it is cheaper than other materials. Thatch is made of every kind of coarse fibrous substance, and its equivalents—rushes, heath or heather, reeds, brush of all kinds when fine enough, broom, and even furze—are all used for the purpose, according to the plenty in which they are found, and the absence of other material. Indeed, in one part of England, where they grow a great deal of brushwood, and manufacture it into hoops for the West India and other tropical trades, to bind sugar barrels with, the hoop shavings and splinters are fastened on the roofs of the labourers' cottages, and make a very tight and lasting, but extremely *bizarre* and ungraceful covering. They are put on to the thickness of at least fourteen to eighteen inches, and as they can neither be smoothed, nor trimmed at the eaves, they look as if the cottages were surmounted by coarse heads of hair, in most extraordinary confusion, and quite disproportioned to the houses.

There is no kind of common "stalky" substance that is not in some way or other used for thatch in Britain, but the chief article, as we said before, is wheat straw. This is used "threshed," for ordinary purposes, and unthreshed for the covering of dwelling houses, ornamental cottages, and other purposes of a superior nature. Unthreshed straw has the heads or ears of the grain cut off, and is then bound in bundles for the thatcher. Threshed straw is drawn by the hand from the heap or straw stack, then roughly sorted into untied portions or parcels called called "hands," roughly combed out with a rake, and piled up "athwart and across," in heaps, well wetted to make it lie close, and finally weighted by placing heavy substances on the top. Here it remains for a few days for the thatcher, and is finally laid on the building without other preparation. The actual method of thatching would take too long to describe in this place, though we may do so in a future article.

Thatching is of two kinds, "over-sparred" and "under-sparred;" the over-sparred takes the least straw, and is used for ricks and other temporary purposes. It is also used in repairing other thatch. Under-sparred thatch is used for permanent roofs.

The chief objection to thatch in Canada will always be, danger from fire. It is, where there are many sparks or chimneys, and where all use fires so extensively as we use them here, a very dangerous roof. It is, however, very warm and effective.

In some places in England, where building materials are dear and straw is cheap, the walls bear a most ridiculous proportion to the roof. Barns are often seen with a dwarf wall of from four to six feet high, and then a monstrous roof, reaching, perhaps, from twenty to thirty feet high, and with a great span. The celebrated "Tithing Barns," near Goodwood Park, South Hants, England, are of this nature, and similar buildings are often seen.

The same preponderance of roof over wall is also seen to a great extent in the low countries of Europe, such as Holland. The roofs are of tiles (of course supported by timber), and are often six times the height of the walls.

Slates are the next principal roofing material, but they will for many years be too dear for farm buildings. There is no doubt that slates form one of the best roofs in the world, and as we are yearly making new discoveries in the geological formation of Canada, slates may yet become a most important aid to the farmer.

Tiles, however, are likely to form the farmer's mainstay. Draining tiles we must have; and where they make drain tiles they can make roofing tiles with a mere change of mould, and either can be burned in a kiln of very simple construction or with bricks, as before described.

In England, many buildings are "tile-hung," that is, walls of inferior materials are covered with tiles to keep off the weather, like our clap boards, or shaped and formed like bricks, when the buildings can hardly be distinguished from the latter material.

VECTIS.

We are not certain that for this climate tiles may not be found more serviceable than even slates, which are very apt to split by the action of our severe frosts.

Veterinary Department.

Injuries of the Horse's Mouth.

Injuries to the horse's mouth are of frequent occurrence, and often prove very troublesome and annoying. In aged horses the teeth are unevenly worn, and become very sharp and projecting, thus injuring the cheeks and gums, and interfering with the process of mastication. The tongue is frequently injured from the bit in hard-pulling horses, and in some cases it is nearly cut in two. The fold of mucous membrane (*frenum linguæ*) which attaches the lower part of the tongue to the floor of the mouth, is occasionally injured by the tongue being violently pulled to one side in the administering of medicines, by careless people; and foreign substances now and again become lodged in the muscular substance of the tongue, towards the base. We recollect a case where a small needle had penetrated the tongue and become embedded there, giving rise to excessive swelling and irritation. The symptoms produced by these injuries are increased discharge of saliva, difficulty in masticating the food, and in severe cases the horse will altogether refuse his food. This is especially the case when either the *frenum linguæ* or the root of the tongue is the seat of injury. The tongue is occasionally swollen and protruding from the mouth, and the secretion has an offensive odour. When the irritation is the result of sharp and projecting teeth, the first symptom often noticed is the horse cudding his hay, which will accumulate between the grinders and the cheeks, in some instances to such an extent that it is necessary to remove it by the hand. As a consequence of this impaired mastication, and also an increased discharge of saliva from the month, the horse soon falls off in condition.

When these symptoms are presented, the mouth should be carefully examined, and in order to do so properly it is necessary to use the balling iron. When the ailment is the result of uneven wearing of the teeth, the remedy consists in the free use of the tooth rasp. If any irritant is lodged in the tongue, it should be removed, and the month should be gargled several times a day with tepid water, and a solution of alum, about one drachm to the pint of water. The horse should be fed on bran mashes for a few days, until the healing process sets in.

Occasionally the mouth is affected with an eruptive disease, called Aphtha or Thrush, which attacks the lips, the cheeks and gums. This disorder generally results from impaired digestion, or a debilitated state of the system, and is frequently brought on by eating hay or oats of an inferior quality. There is swelling of the mucous membrane lining the cavity of the mouth, and turning out of the lips. In a day or two after the first appearance of the swelling, small red spots appear, which finally become filled with pus, and turn to a yellowish tinge, then burst and discharge matter. This irritation of the mouth gives rise to an increased discharge of saliva, and the horse refuses his food.

In the treatment of aphtha a change of food is desirable, and a mild dose of laxative medicine may be given, as two or three drachms of aloes with one drachm of ginger. The mouth should also be gargled once a day with alum water, and the general comfort of the patient well attended to.

Diseases of the Digestive Organs of the Horse.

The pharynx is sometimes the seat of inflammation, in connection with sore throat or inflammation of the larynx, and it is occasionally injured by the careless administration of medicines. Some people are in the habit of giving balls to horses by means of a sharp pointed stick, and not unfrequently the pharynx is punctured, an accident which is speedily followed by acute inflammatory action, and often terminates fatally. The symptoms of this injury are alarming and well marked. The horse is quite unable to swallow either food or water, he suffers great pain, and is very much fevered, the pulse running high; the disease extends to the respiratory tract, and the breathing becomes distressing and laborious. There is also slight swelling externally, and the parts are very tender when pressed. The treatment should be such as to allay the fever and irritation, and this is best done by applying fomentations of hot water externally, which should be applied for hours to afford relief. Demulcents may also be given, and the throat and mouth gargled with a gargle composed of water eight ounces, laudanum half an ounce. The tincture of aconite should be given in doses of ten drops every three or four hours, according to the severity of the attack. We cannot too strongly condemn the practice of giving balls in the manner described, as many valuable horses have been destroyed by that means. Not long ago, one of the finest horses in the United States received injuries in the administering of medicines that proved fatal in the course of a few days,

The œsophagus or gullet is liable to become obstructed, which gives rise to choking. This occurrence is not quite so common in horses as it is in cattle. The obstruction may consist of a piece of carrot, turnip, or an apple; or it may be produced by chopped hay or straw, or by giving too hard balls. Choking may occur in any part of the œsophagus, but the obstruction is oftener situated in the cervical than in the thoracic portion. The symptoms of choking, in most instances, are very alarming. There is active suffocation, and if the animal tries to drink, the water is returned partly through the nostrils: there is spasmodic action of the muscles of the larynx and also of the muscles of the neck, and a discharge of saliva from the mouth, which is greatest when the obstruction is situated in the cervical portion.

In the treatment of choking, endeavours must be made to remove the obstruction; and in some cases, by giving small quantities of oil in gruel, the offending agent may become displaced. The bland fluid lubricates the part, and, in the endeavours to swallow, the foreign body will often slip down. Manipulation from the outside may also cause its dislodgement. In all cases, great care should be taken not to injure the pharynx. If these means fail, the probang must be used. In cattle the probang is easily passed, but in horses it is well to be very careful in passing it. If the probang is used incautiously, the walls of the œsophagus may be ruptured; and when such an accident occurs it invariably proves fatal.

Lice on Cattle.

In compliance with a request from a subscriber for further information on this subject, we once more bring it before the notice of our readers.

There are two species of lice which are said to affect cattle: First, the *Hæmatopinus Eurysternus*. This species is often met with about the head and neck, and, according to Denny, the young ones are more agile than the old. The second species is the *Hæmatopinus ani et vulvæ*, which are found principally on the thighs and under the tail.

Lice appear to be generally in greatest numbers on animals that are in poor and filthy condition; therefore, to remove them, great attention should be paid to cleanliness. Many different remedies may be used which will effectually destroy these insects. A decoction of tobacco, about two drachms to a pint of water, may be used with advantage. Mercurial dressings are also beneficial, but must be used with caution, and only a small surface rubbed at one time. The following formula is also recommended as a safe and effectual remedy:

Staveacre seeds, 4 oz.
White hellebore, 1 oz.

To be boiled in a gallon of water until only two quarts remain, and applied with a brush to these parts where the lice are seen.

The following note on the subject, from a correspondent, also gives a good suggestion, and with the cautions he prescribes the remedy may be safely tried. Red precipitate is a mercurial preparation:—

"Should your prescription fail, I would recommend a trial of red precipitate well mixed in hogs' lard, a teaspoonful of the former to a pound of the latter, applied by dipping the finger lightly in the mixture, rubbing it on the shoulders and back in no more than five or six places at a time. The animal requires to be kept warm during this course, which on that account may be preferable in the warmer seasons of the year. I have seen this course tried several times, and have never known it to fall short of the desired effect."

Veterinary Surgical Operation.

A London (Ontario) paper gives the following account of a remarkable accident and successful surgical treatment, which reflects much credit on the skill of the surgeon, Mr. J. H. Wilson, who last year passed a very successful examination, and received his diploma from the Toronto Veterinary College. Our contemporary says:—

"A remarkable case of veterinary surgery came under our notice a short time ago, resulting contrary to our expectations. The facts are as follows: A team belonging to W. R. Hodgins, of the 16th concession, London, got frightened at some object, and became entirely unmanageable. They ran furiously towards a barn, situated a short distance from where he was using them, and while running through the orchard, which is between the barn and the place of work, the near horse was thrown violently against a large apple tree, the concussion being so great as to fracture the right parietal bone, forcing the same downwards, and overlapping the frontal bone. On examination, it was found that the *dura mater* had been penetrated by particles of spicula, the *arachnoid* and *pia mater* (membranes covering the brain) escaping injury, and pieces of the wood and bark were extracted carefully by the surgeon, and the broken sections of the parietal bone were so adjusted as to cause little or no irritation of the brain. Great credit is due the veterinary surgeon, J. H. Wilson, of the village of St. John, who performed the operation, and saved the life of a valuable animal. This extraordinary operation ought to establish in the minds of the people of this Province the great use and necessity of proper education for those who profess the art of healing horses. Such an Institute is now in Toronto, providing the means, where the veterinary art is taught with great success."

GREASE IN HORSES.—A correspondent from Kelso, Quebec, wishes to learn what is a good remedy for this complaint in horses. Grease in an inveterate form is difficult to cure. In the treatment of all cases strict attention must be paid to cleanliness, and if the irritation is great, apply poultices of linseed meal for a few days, to which may be added a little yeast. The horse should undergo a course of medicine. A drachm of the iodide of potassium may be given once a day, until twelve doses are given. Any mild astringent applied externally will also be beneficial in hastening on the healing process. As we have before mentioned, in all bad cases it is well to call in the services of a qualified veterinary surgeon.

Apiary.

Impregnation of Queens—A Wonderful Discovery.

Intelligent bee-keepers have long understood that the queen bee is impregnated on the wing, that about the fifth day after she is hatched she takes her bridal tour to meet the drones in the air. And however desirable it may have been to control this matter, as we do that of cattle, this fact seemed to preclude all possibility of its ever being done. But since the introduction of Italian bees the minds of bee-keepers have been turned in that direction, in order to discover, if possible, some method whereby the impregnation of the queen could be controlled—some plan that would enable the bee-keeper to cause the queen to be fertilized by such drones as he might select.

It was seen that the advantages arising from such a discovery would be great indeed. There would be no difficulty in keeping Italians pure. Large apiaries could be Italianized in one season from one queen. There would be no loss of queens by going out to meet the drones in the air, as is frequently the case now. For a long time, however, there appeared no probability of such a discovery. Many methods were suggested and tried, only to prove failures. Much to the surprise of many, therefore, it was stated in the *American Bee Journal*, No. 9, for March, 1868, that Mr. Kohler had announced in the *Bienenzeitung*, a German paper, that he had discovered a process to prevent Italian queens from having concourse with common drones, and securing their fertilization by Italian drones exclusively. But as Mr. Kohler was poor and had a large family to support, he was advised to keep the process a secret until assured of compensation for his discovery. It was soon arranged, and eminent bee-keepers were appointed both in Germany and England to receive subscriptions for the process, at 10s. 6d. each, sterling. Learning that Mr. Woodbury, a Devonshire bee-keeper, was one appointed to receive subscriptions, I immediately wrote to him, enclosing the amount required. About the same time, I received from Mr. Gray, of Ohio, an extensive queen breeder, a process which he assured me was the Kohler process, he having obtained it through a friend. I immediately forwarded the same to Mr. Woodbury, who wrote to me, saying it was the Kohler process, also returning me the money.

The process was as follows: The stock containing a young queen to be fertilized was to be placed early in the morning in a dark cellar, along with a stock containing the drones with which it was desirable the queen should mate. Late in the afternoon, when all the drones, or nearly all, had ceased to fly, the stocks were to be brought out and placed on their stands, giving each a teacupful of warm honey. Having been confined through the day, the warm honey would excite them, they would rush out of the hives for a fly, and the queen would be fertilized. Of course, the hive containing the young queen should have no drones in it, unless they are such as you wish the queen to mate with, in which case it would not be necessary to put in another hive containing drones.

As soon, then, as it became known that Mr. Kohler had discovered a process, for which he was to receive a recompense, there appeared in the *Bienenzeitung*, and several other foreign periodicals, full accounts of methods practised by others for securing the same results, which being identical with the Kohler process, Mr. Woodbury and others appointed to receive subscriptions, refused to do so any longer, and returned the money they had already received.

This process, although far in advance of anything heretofore discovered, is not al that is to be desired. It requires the bees to be confined for a day in the very height of the honey harvest, and heavy stocks require time and labour to move them to and from a dark cellar or room. It also requires a large number of drones to ensure fertilization. The queens are still allowed to fly out to meet the drones, and may be lost. I have the pleasure, however, of informing my bee-keeping friends that a process has been discovered by an American lady, who keeps a large apiary, and is a regular contributor to the *American Bee Journal*. By this process all difficulties are removed, and the bee-keeper is enabled to secure the fertilization of a queen by one of four or five drones he may select for that purpose. Though it has cost me some expense and trouble to obtain this process at so early a date after its discovery, yet so soon as I am free from the bonds of secrecy that I am now under, I intend to publish the process for the benefit of my fellow bee-keepers. Though I have never tested it, having but lately obtained it, yet I have full confidence in the veracity of the lady who discovered it. She says that during last season she tested it many times, and not in one instance did the queen fail to become fertilized. I might here say that myself and brother talked over the same plan several times during last season, but through a pressure of business failed to try the experiment. So while we were thinking, our Yankee lady cousin made the discovery, a discovery which must revolutionize the whole system of bee-keeping.

Through the assistance of a friend, she is endeavouring to secure some compensation; therefore I am not at liberty to disclose it. I think, however, she will fail in doing so, for to my certain knowledge, several bee-keepers in the United States are in possession of the secret. I shall, no doubt, be able to publish it in time for next season's operations.

Brooklin, Ontario.

Stock Department.

Early Fatted Hogs.

To the Editor.

Sir,—As the time is about at hand for making arrangements for the coming generation of swine, I should like to call the attention of our farmers to some points :—

1st. We require a larger number.

2nd. We shall require them very early the coming season.

3rd. I would very strongly urge on farmers to have a good breed, and this I should think a matter of easy attainment, as in every township there is a good boar, Berkshire, Essex, or some improved breed, and it would pay a farmer ten times over to drive twenty miles and pay $2 for service.

4th. Castrate very early. It is ruinous to the quality when they are allowed to run till they are 5, 6 or 7 months old.

5th. Spay the sows not intended for breeding, for they will fatten twice as quickly.

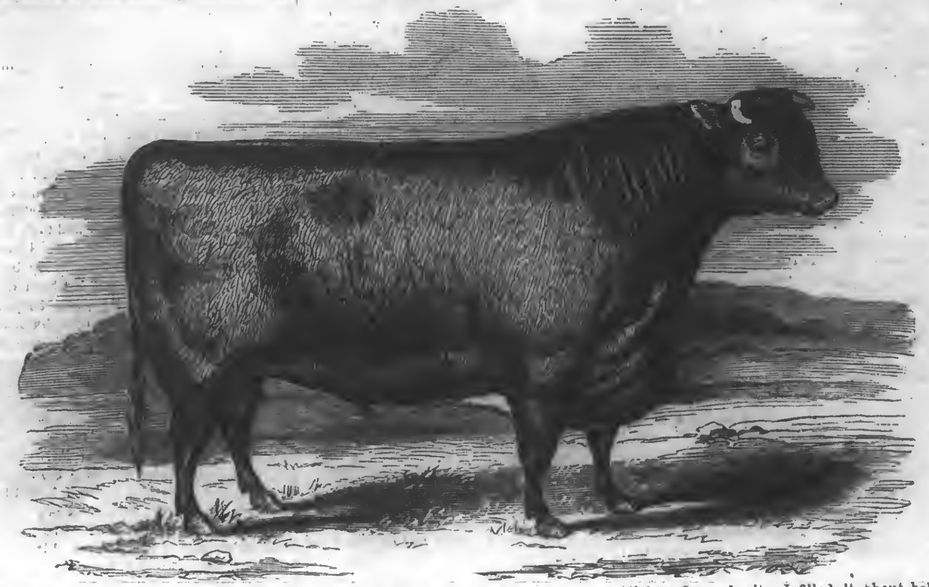
6th. Be sure not to let them run in the woods; it is ruinous to the meat, and it cannot be profitable to the farmer. I would particularly recommend farmers to grind the food for hogs ; they do so much better on it than on whole peas.

Attention to the above will be the means of raising the standard of Canadian pork in the English market. We often hear the remark that it does not pay to fat hogs, and in many cases this is true. It does not pay to have a hog running round for two years and only weigh 200 when killed, but it does pay to keep good pigs and have them weigh 200 lbs at six months old. The Berkshire are a capital breed ; they are healthy and hardy, and are fit for killing at six months old ; and if a great weight is desired they will carry it.

Most of the heavy hogs are not only heavy but coarse, the shoulders and hams of which are so heavy as to be almost unsaleable. If there never was a hog over 300 lbs, it would be a good thing. A Berkshire pig of that weight, thoroughly fat, makes as good mess pork as can be desired.

W. DAVIES.

Toronto Packing House,
Jan. 11, 1869.



Short-horn Bull "Minister."

In the January number of the Canada Farmer we gave a portrait of "Sweepstakes," a very successful prize bull belonging to Mr. J. H. Pickerell, of Harristown, Illinois, who lately visited this Province, and made extensive purchases from the best herds in the country. Mr. Pickerell was accompanied in his tour by another enterprising American breeder, Mr. W. R. Duncan, of Towanda Meadows, Illinois, who has now, partly by judicious purchases, and partly by careful breeding, collected an excellent herd of short-horn cattle. The annexed illustration is a portrait of the fine bull "Minister," at the head of this herd. His colour is red. He was bred by R. A. Alexander, of Kentucky. Since he came into Mr. Duncan's possession, he has been the winner at County and State fairs of prizes amounting, in the aggregate, to upwards of $1,500. His calves have also repeatedly gained distinction in the show-ring.

My Experience in Fatting Berkshires on Pea Soup.

Last year I put up five small-breed Berkshires to fat. They were about a year old, and had not been kept well, as we had but little feed. After the stubbles were picked clean, I determined to try pea-soup to fatten them. At that time they were in fair order, though rather small for their age. I dug a hole in a cradle knoll, and placed a potash kettle over it, with just sufficient room to light a fire under it. I filled it about half full of water, and fired up. The water was soon warm, and I went to the barn for some peas, after putting in what few I had in the bag, and on my return was rather alarmed at the extraordinary demonstration I witnessed. There were no less than five pigs in the kettle, attracted by the peas in the bottom, and as the water was rapidly getting warmer each moment, the place was evidently literally getting too hot to hold them. The sloping bottom prevented their jumping out, and had the water been hot, all would have been scalded. With some difficulty I pulled them out one after another, and great wiggling of tails was the result. They were not much hurt, but I lost no time in fixing a strong cover to the kettle, as I did not think it advisable to scald pigs before killing them. From this time forward I boiled the peas every day, and my Berkshires throve amazingly. After eating just five bushels of peas each, they were killed, and made 1,275 lbs. of as fine pork as I ever saw. The value of the pigs, before fattening, was estimated at $6 each, and that amount was offered for them for the American market, then very good. The peas were worth 60c a bushel.

The account would stand thus :

	Dr.	
5 Berkshire hogs, at $6		$30
25 bushels peas, at 60c		15
		—$45 00
	Cr.	
By 1,275 lbs. of pork at 6 cts. per lb		$76 50

Showing a profit of $31 50, or about $6 25 each. The common idea is, that to feed pigs on peas does not pay, as the pigs and peas are worth more than the pork ; but my case was different. It certainly paid to raise pigs at $6 each when put up to feed, and it certainly paid to fat them on pea-soup, at a profit of $6 25 each.

C.

From some carefully collected and very extensive notes made by Lord Spencer on the period of gestation of 764 cows, it resulted that the shortest period of gestation when a live calf was produced was 220 days, and the longest 315 days ; but he was not able to rear any calf produced at an earlier period than 242 days. From the result of his experiments it appears that 314 cows calved before the 284th day, and 310 calved after the 285th, so that the probable period of gestation ought to be considered 284 or 285 days.

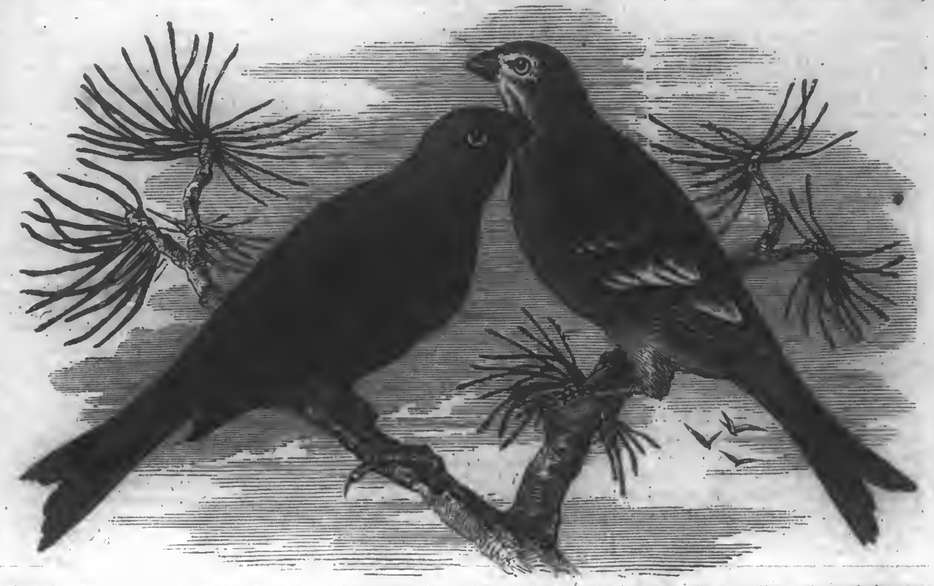
Natural History.

The Pine Grosbeak.

(*Strobilophaga enucleator.*)

During the present winter we have been favoured by a visitor from the north, the Pine Grosbeak.

This handsome bird has been seen in several parts of the Province in considerable numbers, and has contributed not a little to enliven our woods. Its home in the summer is in the northern parts of our own continent and those of Europe and Asia. It generally visits Canada and some of the northern United States in the winter, and returns in the spring, passing Hudson's Bay in May.



It is a comparatively large bird, measuring about nine inches in length, and its plumage is unusually gay for the regions which it inhabits, the head, neck, and breast being of a rich crimson hue. The feathers of the back are black, edged with crimson. The female is somewhat smaller in size, and of much more sombre plumage, the prevailing colour being slate or grey, with a greenish yellow tinge in part taking the place of the crimson markings of the male. The young males very much resemble the females, so much so, indeed, as not to be easily distinguished, except on close examination, when they will be seen to be a little larger, and to have rather more and a somewhat brighter tint of the greenish yellow colour, especially along the back.

The male and female birds are represented in the accompanying illustration. The absence of colour in the engraving makes the difference less conspicuous than in nature.

These birds live in pine forests, feeding on buds of various kinds, and on the seeds of the fir cones. Their note is sweet and clear, and Wilson, who had one for some time in captivity, says that it would sing for a whole morning, and imitated several of the notes of a Red-bird which hung near it. He describes it as being exceedingly tame, and states that it would ask for food or water with a continuous, melancholy, anxious cry.

Another bird, much smaller in size, but with plumage remarkably like that of the Grosbeak, has been frequently seen in Canada during the past mild winter. The similarity is so close that they have been commonly mistaken for a smaller variety of the same bird, whereas they are quite distinct, and belong to a different genus. This smaller bird is the White-winged Crossbill (*Loxia leucoptera*), and it can at once be distinguished by its very peculiar bill, which looks almost as if it were a deformity, the two mandibles crossing each other near the tip. This peculiarity, which gives the name to the species, is no *lusus naturæ*, however, or freak of nature, but a wise provision to enable the bird to extract more readily the seeds of fir cones, &c., from the situations in which they are embedded.

The White-winged Crossbill is a much rarer bird with us than the Grosbeak, yet both have been frequently seen together in flocks of various sizes during the present winter, in several parts of the Province.

Utility of Snowbirds.

To the Editor.

SIR,—Observing a few days ago a number of snowbirds perched on my apple-trees, seemingly very industriously employed, I felt curious to know what they were about. Taking care not to disturb them, I took a spy-glass, and saw they were busy pecking at the stems of the branches, but not touching the buds. I concluded they were picking off the lice, which, owing to the warm summer, seemed to have greatly multiplied.

After they left, I examined the trees, and found they had cleared them in good style, choosing the worst for their operations. The branches presented a white, speckled appearance after the operation, on the spots where the lice had adhered.

The surface of the snow being very crusty, and smooth, the shells lay thickly upon it, giving it the appearance of being thickly dusted with coarse pepper. Out of a few dozen of these shells picked from the surface of the snow, I could not with a microscope observe an egg in one.

This trait in the character of these birds not being generally known, I thought it might be interesting to some of your fruit-growing subscribers.

I have also observed what I call small flocks of canaries all through the winter. Their note is exactly the same, although they are darker in plumage than in summer. Perhaps some of your corresponding ornithologists may have observed the same, and will enlighten us on the subject, as I think it very uncommon. J. McL.

Owen Sound, February, 1869.

NOTE BY EDITOR.—We have long been of opinion that the Snow-birds (*Fringilla hyemalis*), as well as other members of the Finch family, are eminently insectivorous, and hence useful to the agriculturist. They may, and probably do, often pick up a useful insect such as a Lady-bird, a Syrphus fly larva or a Spider, but still, with all due deference to Mr. Walsh, we believe they do more good than harm. In the case referred to by our correspondent, they appear to have made a severe raid upon the eggs of the apple-tree Bark-louse (*Aspidiotus conchiformis*), which are covered by a shell-like scale, the secretion of the female insect. They would probably devour also the eggs of the Apple Plant Louse (*Aphis mali*), which are laid in the interstices of the bark, and any other insect which chanced to be up and about on the occasional mild days of winter.

The canaries referred to are, as our correspondent supposes, the same birds as we have with us in summer, but in very different plumage. Few who see these dingy little birds about their gardens and orchards in winter fancy that they are the same as the gay yellow and black goldfinches, or wild canaries, of summer. Yet such is the case, as ornithologists well know. They, too, are useful birds, devouring the seeds of thistles and other weeds, and multitudes of plant lice and other minute insects.

Poultry Yard.

The Use of Poultry Shows.

To the Editor.

SIR,—The Ontario Poultry Society are trying to come to the front once more with their fourth exhibition, and their efforts have been most liberally aided by donations from several firms in this city, and there is every reason to expect that Hamilton and London will also contribute towards the prize list. But whilst soliciting contributions for this purpose, we are met with various objections (I use the pronoun "we," not that I have the least personal interest in the proposed exhibition, but that simply I wish a good beginning successfully carried out.) These objections are made, in some cases, even by those who themselves keep poultry. One says:—"I only keep common birds, and do not believe in your fancy articles." Now, the Society's aim is not to encourage poultry as a fancy merely, although in many instances such will be the result, but to foster a branch of stock-keeping that might prove a lasting, solid advantage to the country. What I am writing is a thrice-told tale, has been already written by myself and others, and I am afraid will yet have to be reiterated. People who keep fowls might, at least, as well have good saleable articles as mongrel rubbish, at the same cost.

Again, another will say, "what is the use of your points? Why is a Spanish bird with less comb not as good as another? Why should Aylesbury ducks be rejected because their bills have tinges of yellow and black spots? Why withhold a prize from Dorkings which have not five toes?"

There is an excellent reply to this sort of reasoning in the *Journal of Horticulture*, March 3, 1863, which I shall quote in my aid:—

"It has been necessary to lay down certain rules, which have been admitted for some years. The great end they answer is to form well defined marks, which may guide the enquirer and beginner. The use of poultry shows has been to publish the merits and properties of divers breeds, and to point out those that are fitted for certain soils and certain markets. The characteristics of a breed being pointed out, a purchaser cannot be easily deceived as to whether it will suit him or not. He will not buy a Dorking without five toes; but if he were to be told that Dorkings with four are as good as those with five claws, he has nothing to guide or protect him. He is at the mercy of any one whose fowls he sees for sale. Or take the Aylesbury duck. If the buyer is told the bird must have a pale bill, he will not buy one lacking that mark. If any bill will do, every white duck, to the uninitiated, becomes an Aylesbury. These are but two instances; many more could be given."

Has any good quality been given up to attain the standard of excellence as regards points? Have Dorkings lost size or constitution? Have ducks diminished in weight or lost appearance? Dorkings have gained much in size, and in weight over two pounds each, while Aylesbury ducks, whose average weight two years since might be three to four pounds, now generally weigh four to eight pounds.

Again, take Pencilled Hamburghs. Roup was thought to be their natural state. People avoided the breed. There was no inducement to take pains with them, till competition and the requirements of exhibitions supplied the spur, since which time they have been shown in perfect colour, shape and markings, and strong enough to bear any trial in the way of climate. These are facts that speak for themselves.

Before I conclude, I should like to try and persuade those that now keep fowls not good enough, as they say, for exhibition, but an inferior lot, to try some recognized breed suited to their taste and means. They will cost no more to feed than the mongrels, and will be infinitely more remunerative in the sale of eggs; or by sending to exhibitions two or three picked from the lot, a price can be obtained which will pay for the consumption of food by all the others.

I have kept, myself, fowls to some extent for home consumption. They cost something to feed. I cannot say if they paid or not; but on getting a pure breed, and picking out a few and exhibiting them, I was paid more than the keep of all the rest, and had eggs and poultry on table gratis, or next to it.

I trust these facts will convince sceptics, induce the support of poultry exhibitions and improvement of the breed, and lead to the abandonment of that heterogeneous mixture of sorts that results in a mongrel race of fowls, and keeps our markets badly supplied with the wretched specimens we are constantly meeting with.

If a thing is worth doing, it is worth doing well, as my grandmother used to tell me. Every man that keeps poultry should keep good birds, and every grain and feed dealer should do his best as well to support the exhibitions of poultry; and need I say, the farmer and his family, as sellers of grain and eggs, should do likewise.

F. C. HASSARD.

Ontario Poultry Association.

The Ontario Poultry Association will hold their fourth exhibition of poultry and pigeons in the Agricultural Hall, Toronto, on Wednesday and Thursday, April 21st and 22nd. It was a disappointment to many poultry fanciers that no exhibition was held by this Society last fall, but it is confidently expected that the ensuing spring show will outrival any of its predecessors. The number of persons who take an interest in poultry is increasing in this country, very marked improvement is manifest in the various breeds of fowls, and a number of fresh importations from Europe have been made since the last

exhibition. Many friends of the Association have shown a laudable liberality in contributing to the prize funds, and the Society have every reason to expect a successful show in April, an expectation which we cordially hope will be fully realized.

Persons intending to exhibit can obtain full instructions concerning the rules of competition by applying to the secretary, Mr. T. McLean, Box 25, P. O., Toronto.

For the information of those who have birds to exhibit, or who wish to become purchasers, as well as to furnish a useful guide to Agricultural Societies, we give below the Prize list, omitting the repetition of the amounts, which, in the class of poultry, are $4 for the first, and $2 for the second prize: and in pigeons, $2 and $1 respectively.

PRIZE LIST.

POULTRY.

BIRDS TO BE SHOWN IN PAIRS.

CLASS 1—*Cochin China.* Buff or Cinnamon.
CLASS 2—*Cochin China.* White or any other colour.
CLASS 3—*Brahma Pootra.* Dark.
CLASS 4—*Brahma Pootra.* Light.
CLASS 5—*Dorking.* Coloured.
CLASS 6—*Dorking.* White:
CLASS 7—*Spanish.*
CLASS 8—*Game.* Black-breasted and other Reds
CLASS 9—*Game.* Duck-wing, Greys and Blues.
CLASS 10—*Game.* White, Pile and any other variety.
(Prizes given by A. McLean Howard, Esq.)
CLASS 11—*Hamburg.* Gold or Silver Pencilled.
CLASS 12—*Hamburg.* Gold or Silver Spangled.
CLASS 13—*Polish.* Gold or Silver.
CLASS 14—*Polish.* Any other variety.
CLASS 15—Houdan, Crevecœur, La Fleche, and other French fowl—any age.
CLASS 16—*Bantams.* Gold or Silver Laced.
CLASS 17—*Bantams.* Game and any other variety.
(1st prize given by Wm. T. Goldsmith, Esq., St. Catharines).
CLASS 18—*Turkeys.* Any variety.
CLASS 19—*Ducks.* Aylesbury.
CLASS 20—*Ducks,* Rouen.
CLASS 21—*Ducks.* Any other variety.
CLASS 22—*Geese.* White.
CLASS 23—*Geese.* Coloured.
CLASS 24—Any other variety of fowl not mentioned in above classes—any age.

PIGEONS.

BIRDS OF ANY AGE, TO BE SHOWN IN PAIRS, EXCEPT CARRIERS AND POUTERS.

CLASS 25—*Carriers.* Cocks. Any colour. (One prize.)
CLASS 26—*Carriers.* Hens. Any colour. (One prize.)
CLASS 27—*Pouters.* Cocks. Any colour. (One prize.)
CLASS 28—*Pouters.* Hens. Any colour. (One prize.)
CLASS 29—*Tumblers.* Any variety.
CLASS 30—*Jacobins or Frills.* Any colour.
CLASS 31—*Fantails.* Any colour.
CLASS 32—*Barbs.* Any colour.
CLASS 33—*Turbits.* Any colour.
CLASS 34—*Trumpeters.* Any colour.
CLASS 35—Any other variety of pigeon not mentioned in the foregoing classes.

The Judgment of Poultry.

To the Editor.

SIR,—Your correspondent, F. C. H., has written a letter upon this subject which will be read with interest, and thorough approval by every poultry amateur of the right sort F. C. H., may congratulate himself upon not having sent any of his Cochins to the last Provincial Exhibition in Montreal. They would not have been noticed by the judges, or if they had, they would have been awarded the prize for Jersey Blues, perhaps, as no animals of that species were shown, though under the special patronage of those who made out the prize list.

I was myself awarded a prize for Cochins, for a pair of dark Brahmas, at the last Exhibition, and to judge from appearances, no pains are likely to be taken to prevent the recurrence of such mistakes, or "jokes," as they were termed. Henceforth dark Brahmas are to be Cochins, and Cochins no fowl at all; Jersey Blues to remain as they are until further orders.

At the Exhibition referred to, the rights of exhibitors were ignored in the most arbitrary manner by the appointment of judges, who in fact acknowledged that they did not know one variety from another, and who awarded prizes for birds that were not exhibited.

Nor were exhibitors in other classes treated with more consideration. I sent my Alderneys, fresh from their triumphs at home, yet, although they had been entered weeks previous to the Exhibition, when taken to the grounds, there was no place for them save a muddy shed which had been used as a place for washing cattle, without divisions or anything to which the cattle could be tied. No notice whatever was taken of the animals by the judges, but when it was seen that the Alderneys formed an attractive feature in the Exhibition, a tardy and graceless recognition of their merit came from the Board of Agriculture of Lower Canada. In the course of two or three days, a card with honourable mention printed upon it, was stuck up behind their tails, and I was also notified that a silver medal had been awarded, a medal which I have not received, although five months have elapsed since the Exhibition. My experience, and that of other exhibitors, showed that the managers of the last Exhibition passed over without remark many abuses and acts of injustice.

S. SHELDON STEPHENS.

Montreal, Feb. 4, 1869.

Diseases of Poultry—Swollen Feet.

To the Editor.

SIR,—I am well acquainted with the disease mentioned by your correspondent in the CANADA FARMER of February 15th. I have not found it permanently to injure the birds. Beyond a slight lameness, they have not suffered by it. The hard swelling at the root of the toes becomes chronic if left alone, and the fowl assumes its usual paces. Outward applications are useless, and, I should think, to operate on the foot would be injurious. I have a hen which is always in a state of swelled foot. When she is quite unable to walk or stand, I place food and water near her, lift her upon the perch at night, and in other ways nurse her. She ceases to lay for a few days, but begins again all the better, and runs and walks till another attack comes on. She is never without the enlargement. Bumble-foot is a totally different affair, and requires prompt treatment. Bread poultice in the first stages, till the ulceration is developed. Then open the foot and cut away all the wart-like substance, allowing it to bleed freely. Change the poultice every day, with warm bathing, and encourage the foot to bleed. If matter seems forming, open the wound anew. Do not leave off the poulticing until the foot is healed and healthy-looking. Keep the bird all this time on nice clean straw, and give good food, with a little sulphate of iron in the drinking water. If the disease is taken in time, and the poulticing well kept up, the cure is certain. Rheumatism and cramp, with inflammation of the heart and lungs, which almost always follows, is a most dangerous disease, and one which has hitherto baffled all my efforts to cure. Fowls contract this disease from walking in and drinking snow water. I have lost two valuable Brahma chickens and a hen from it. Now I have a Houdan pullet under treatment. If she recovers, after seven days without being able to stand or eat, it will be a wonderful case. The inflammation flew to her heart and lungs, and the toes and legs contracted.

CHANTICLEER.

Chicken Hatching and Feed.

(To the Editor.)

SIR—The remarks on the above subject in your journal will be of some service to many. I have practised the process of hatching chickens more or less for some years, but I generally put them under the hen, as I think they dry more naturally there than in an oven. I do not at all agree with the writer of the article that Brahmas and Cochins are bad mothers. I think quite the reverse, after an acquaintance of some twelve years with Cochins. If you will keep the eggs properly moistened, and also get them fresh, your artificial handling will not be required. There is another important point. I say never put more than eleven eggs under any hen. Nine is my number, and if the eggs are fertile, nine chicks will appear. You can not guarantee more out of thirteen; because if the nest is deep, when hatched they are all huddled together at the bottom, and some will be squashed; and if the nest is very shallow, you will find an egg showing at various periods of incubation. This is consequently chilled, and probably spoilt; and it is not always the same egg. Many are

thus lost. At an average you will get more out of nine eggs than thirteen.

The writer does not consider four or five a brood. Well, that depends on the time of year. Late or early in the season, I never wish to see more than four birds with any hen. They cannot cover more at four weeks old, and then they get lung disease and die You must hatch early if you wish to do anything at chicken shows, and the cold will not hurt them if they have the mother to run under, and at the commencement of the year a hen cannot shelter properly more than four chicks. In May, June and July, it is different, as they then do not require so much care.

Notwithstanding these criticisms, I consider the communication a very valuable one to many, and trust that no one will expose their ignorance of an important subject by a laugh or sneer, as I can certify that many birds I have raised owed their existence to my having extricated them from the shell; but let the eggs be fresh, and wet them daily, and they will be out on the 21st day, before you are up.

F. C. HASSARD.

HOUDANS.—A subscriber wishes to know where he can obtain any Houdan fowls in Canada. We believe that Mr. Varley, of the 13th Hussars, now stationed in Toronto, has some imported birds of this variety yet to dispose of.

EGGS FOR HATCHING.—We frequently have enquiries as to where eggs of a pure breed may be procured. We have pleasure in referring parties in quest of such articles to the advertisements of Mr. T. McLean, the Secretary of the Poultry Association, and of Mr. Acres, also a member of the same society.

Fowls exposed to dampness are apt to be troubled with catarrh, which will run to roup if not attended to. Red pepper mixed with soft feed, fed several times a week, will remove the cold. Pulverized charcoal, given occasionally, is a preventive of putrid affections, to which fowls are very subject.

Chickens hatched in the early spring, where properly protected and tended, are generally more vigorous and healthy, grow more rapidly through the summer months, and make larger fowls than those arriving in later portions of the breeding season. And, furthermore, pullets which come in the early spring are so well matured that they will commence laying in the ensuing fall, and lay through the winter, if they are duly fed and protected.

GOLDEN PHEASANT.—Mr. Whitehead, of Bradford, enquires, "where he can procure a setting of "golden pheasant" eggs, also a setting of game of the blue kind. We are not quite sure whether our correspondent means golden pheasant fowls, golden pheasants, or gold spangled Hamburghs, which sometimes go by that name. If either of the former is meant, we are not aware that they could be procured in Canada. Hamburghs could no doubt be supplied by Mr. McLean Howard, of Toronto, who would also, probably, furnish the game fowls.

Entomology.

Ravages of a Grape Insect in New York.

That a man should desire to raise his own Isabellas is laudable and praiseworthy, and I see no reason why such desire should exist exclusively in the breasts of our bucolic friends. The inhabitants of New York, as a general thing, clearly, are of the same opinion, as is evidenced by the number of grape vines ornamenting the doors and trellis-work of the houses of our citizens; not, of course, in the benighted regions of Wall Street, but up town, say from 16th street northward. A friend of mine, residing in 34th Street, showed me, in March last, a very fine vine, which he calculated would produce him sundry pounds of very choice grapes; and in the pride of his heart, he invited me to "call along," occasionally, and feast my eyes on the gradual development of the incipient bunches. Thinking that August would be a good month for my visit, I "called along," wondering in my mind whether my friend would, when the time of ripe grapes came, desire me to help myself out of his abundance, or whether he intended to surprise me with a little basketful of nice bunches, garnished with crisp green leaves. The first glance at the grape-vine banished all doubts on this point. There was an abundance of bunches on the vine, in a rather miniature condition, of course, but of foliage there was not a trace. Of course, I expressed my surprise, though, for certain reasons, I felt none, and asked my friend why he selected a species of vine for shelter, ornament and use which produced no foliage. He rebuked my ignorance pretty sharply, and told me that a few weeks before the vine was covered with leaves; but, for some inexplicable reason, they had all disappeared—eaten, he guessed, by something. He guessed right. There were at least a hundred of the larvæ of *Alypia octomaculata* [a rare insect in Canada, ED.] the rear-guard of a mighty host, wandering about the branches, apparently for the purpose of making sure that no particle of a leaf was left undevoured. Pretty little things they were, with harmoniously blended colours of black, yellow and blue; but so terribly destructive. I had the curiosity to walk through all the streets of the rest of Third Avenue, as low as 23rd Street, and every one was in the same predicament. If grape leaves, instead of fig leaves, had been in request for making aprons, and our Alypia had been in existence at the time, I doubt if in the whole of the garden of Eden enough material would have been found to make a garment of decent size. The destruction of the crop for 1868 was complete.

This was bad; but it was not half so bad as the helpless ignorance which possessed nearly all the unfortunate owners of vines. Scarcely one that I conversed with had the remotest idea of the cause of the disaster; and when I explained that it was the caterpillar of a beautiful little black moth, with eight whitish yellow spots on its wings, which had eaten up the foliage, my assertion was received with such a smile of incredulity as convinced me that there is no use in trying to bumbug such very sharp fellows as are the New York grape-growers.

It is a little remarkable, however, that the destruction was confined to the eastern part of the city. I saw several luxuriant vines on the western side; and across the river at Hoboken, and Hudson City, not a trace of the insect was discernible.

The insect, then, is very local in its habits, and it is a day-flier; and from these facts, I infer that its ravages may be very materially checked. A little poisoned molasses, exposed in the neighbourhood of the vine, would operate on the perfect insect, while a good syringing with soft soap and water would bring down the caterpillars effectually. I should like some one to try these remedies; and if their gratitude for my good advice should be so exuberant as to require an outlet, why, I have no objection to receiving a few bunches of their first ripe grapes, if such a step would afford them any relief.—*W. V. Andrews, in the American Naturalist.*

Ravages of the Midge in 1868.

The following is the official account of the ravages of the wheat-midge in this Province during the past year, compiled from the "Report of the Commissioner of Agriculture and Arts of the Province of Ontario, for the year 1868." It is contained in the analysis of crop returns furnished by the Secretaries of the various Electoral Division Agricultural Societies.

ALGOMA.—The midge has not made its appearance.

BRUCE, SOUTH RIDING.—First season of appearance of the midge. Damage supposed 20 per cent.

BRUCE, NORTH RIDING.—Effects of midge considerable.

BOTHWELL—25 per cent. damage by the midge.

BRANT, SOUTH RIDING—Not much damage by the midge.

CORNWALL.—No mention of the midge.

DURHAM, EAST RIDING—From 5 to 10 per cent. damage by the midge.

ESSEX.—Damage by the midge 25 per cent.

ELGIN, EAST RIDING.—Very little damage done by the midge.

FRONTENAC.—Damage by the midge considerable.

HASTINGS, WEST.—Damage by the midge trifling.

HASTINGS, NORTH.—No damage reported by the midge.

HASTINGS, EAST.—No mention of the midge.

HURON, SOUTH RIDING.—Full wheat and much of the spring wheat received 50 per cent. damage from the midge.

HURON, NORTH RIDING.—Damage by the midge, say 33 per cent.

HALDIMAND.—Damage to wheat by midge about 8 per cent.

HALTON.—No mention of the midge.

KENT.—Fall wheat free from damage by midge. Spring wheat damaged by the midge.

LAMBTON.—Damage by the midge from 15 to 30 per cent.

LANARK, SOUTH.—Wheat 20 per cent. damaged by the midge.

LANARK, NORTH.—Not much damage by the midge.

MIDDLESEX, EAST.—Damage by the midge not mentioned, but the following note by the Secretary of the Society is appended:—"It has long been my opinion that if the old Mosaic Law were enforced, and farmers were prohibited from sowing white straw crops each seventh year, we should thereby get rid of the midge and save millions of dollars to the country. I believe I could easily prove this did space permit."

MIDDLESEX WEST.—No mention of the midge.

MIDDLESEX, NORTH.—50 per cent. of the crop damaged by the midge.

MONCK.—No mention of the midge.

NORFOLK, NORTH.—Fall wheat not much damaged by the midge. Spring wheat nearly destroyed, the crop only averaging 5 bushels per acre.

NORTHUMBERLAND, WEST.—No mention of the midge.

ONTARIO, SOUTH.—Severe damage by the midge.

OXFORD, SOUTH.—Not much damage by the midge.

OXFORD, NORTH.—In early-sown spring, 25 per cent. damage by the midge; in late-sown, very little.

PEEL.—About 30 per cent. damage by the midge.

PETERBOROUGH.—Wheat very little damaged by the midge.

PRESCOTT.—Wheat damaged by the midge

PERTH, SOUTH.—Wheat, both spring and fall, considerably injured by the midge.

RENFREW, NORTH.—Wheat not damaged by the midge.

RENFREW, SOUTH.—Not any damage by the midge.

SIMCOE, NORTH. — No mention of midge.

VICTORIA, NORTH.—Damage by midge perhaps 20 per cent.

VICTORIA SOUTH.—"Platt's midge-proof" tried, but did not resist the midge. 20 per cent. damage by the midge.

STORMONT.—Scarcely any damage by the midge.

WATERLOO, NORTH.—Nearly two-thirds of the "Soule" or "white chaff" wheat destroyed by the midge.

WATERLOO, SOUTH.—No mention of the midge.

WELLAND.—Ditto.

WENTWORTH, NORTH.—About 20 per cent. damage by the midge.

WENTWORTH, SOUTH.—Fall wheat not injured by the midge. The spring wheat injured 25 per cent.

WELLINGTON, SOUTH.—Scarcely any damage by the midge.

YORK, WEST RIDING.—Not over 5 per cent. damage by the midge.

YORK, EAST RIDING.—But little damage done by the midge.

YORK, NORTH RIDING.—Not much injury by the midge.

From the remaining Societies no crop return is reported, which is much to be regretted. It will be observed from the above returns that, except in some few favoured localities, the midge has not disappeared to the extent that was fondly anticipated, but that its ravages, on the whole, have been something frightful to contemplate.

The Meal Worm.

"R. P.," writing from Ashworth, desires to be informed how to prevent a scaly worm, about an inch long, from breeding in his flour bins in summer. He says that he has a good bin himself, and some of his neighbours have them almost air-tight, but still they are unable to keep out the nuisance.

Our correspondent has not sent us any specimens of his insect trouble in any of its stages, whereby we might have known with certainty its order and species. There is, however, an insect called the "Meal-worm," that is so common in flour and meal, that we do not hesitate to ascribe his trouble to it. Should we have guessed wrongly, perhaps he will make good his omission by sending us some specimens of the worm.

The Meal-worm (*Tenebrio Molitor*, Linn.), like many of our greatest insect nuisances, is an imported animal from the old world, but by no means one of the kind of stock that tends to the improvement of the country. In this case we have the satisfaction—if we are selfish enough to think it a satisfaction—to know that America has given Europe, in this particular, "tit for tat." They have sent us their *T. Molitor*, and we have returned the compliment by sending them *T. Obscurus*, both of which are very destructive to all kinds of flour and meal. Mr. Carter says that the American worm, introduced in American flour, is now very abundant in London and the Provinces, and that it prefers the sound, dry flour, while their old *Molitor* is good enough to show a preference for that which is damp or damaged.

The worms of both species are very much alike, so that the same general description will answer for either. Though they belong to a totally different family (*Tenebrionidæ*), they yet bear a very strong resemblance to the well-known Wire-worms (*Elateridæ*), being, like them, hard, smooth, and cylindrical, of a shining yellow or pale brown colour, with russet bands on the rings of the body; they have two short feelers (antennæ) in front, and six legs near the head.

(Fig. 1.) When full-fed, they enter the pupa state (Fig. 2.), during which they neither eat nor move about, and at length turn into black beetles. These beetles (Fig. 3.) are nearly three-quarters of an inch long, oblong-oval in shape, of a deep black or very dark chestnut colour; the European species is a little polished and shiny, while the American is quite dull, without any gloss; the former is much the most common and destructive in this country. We have found these beetles swarming in flour-mills and store-houses in all parts of Canada, and not the slightest attempt appears ever to be made to destroy or keep them out. In one country mill, a few years ago, we saw a heap of meal perfectly alive with the beetles and worms, but the owner did not appear to care in the least. There is no doubt that they destroy hundreds, aye, thousands of dollars' worth of our most valuable article of food every year; and not only that, but what many will think still worse, we are quite sure that a very large number of these insects are annually ground up with the wheat, and enter into the composition of our bread!

For this, like all the nuisances about a house, cleanliness is the grand remedy. We can hardly help sometimes getting the eggs or larvæ of this insect in our flour from the mill; but a farmer who takes his own grist can, if he chooses, be sure of its cleanliness, and then, by the use of air-tight vessels or bins, keep out the intruder from his flour. When a bin is already infested with the pest, it should be thoroughly cleaned out, and then scalded with boiling water, or fumigated with sulphur. The lid of the bin should never be left open in the summer time, as then the parent beetles are constantly on the wing, "seeking what they may devour."

Anti-Curculio Plums.

In a recent number of that valuable publication, the *American Entomologist*, mention is made of two varieties of plums that may be successfully grown without any trouble from the depredations of the curculio:—

"The first of these is the Columbia plum, a variety of the European species (*Prunus domestica*). The second is the Miner plum, otherwise known as the Hinckley plum, Isabel plum, Gillett plum, Townsend plum, Robinson plum, &c., which is a cultivated variety of one of our American wild plums, distinguished by botanists as the Chickasaw or wild-goose plum (*Prunus chicasa*) The native home of this wild species seems to be the South-western States; but Dr. Latham quotes it as occasionally found in Illinois. It is altogether different from the common wild plum of the west (*Prunus Americana*), which has a much less elongate leaf, and differs in various other respects."

The Columbia plum is stated to be round, fully two inches in diameter, and to ripen in August in South Illinois. It is only of the second quality, either for cooking or eating, fetching $10 or $12 a bushel, when the best varieties command $16. The curculio is said to puncture and lay its eggs in this plum as freely as in others, yet the larva that hatches out is almost invariably drowned by the exuberant flow of juice that is peculiar to this variety.

The Miner plum is described as a deep red, round plum, about one and a half inches in diameter, of a firm texture, with a rather tough and thick skin. In Wisconsin it ripens from the last of September to the beginning of October. It is only worth in the West from $4 to $6, when the best cultivated varieties sell for $12 or $16; it cannot, therefore, be deemed even second-rate. Still, on the principle that "half a loaf is better than no bread at all," it may be safely recommended to those who have neither the time nor the opportunity to grow prime fruit.

Greenhouse Pests.

The Mealy-bug and the Red Spider, as we hear from the best authority, will stand any amount of tobacco smoke, while Plant-lice (*Aphis*) are easily killed by tobacco smoke. The Red Spider, however, may be got rid of by exposing the infested plants to the rain, and the Mealy-bug by a wash of creasylic soap, sufficiently diluted not to injure vegetation. Cresylic soap, a very useful agent for the destruction of many kinds of insects, can be obtained from the St. Louis Coal Tar Company, Third Street, St. Louis, Mo.—*American Entomologist.*

A Large Curculio.

In the Canada Farmer of July 15, 1868, p. 215, we mentioned that we had received a specimen of a large snout-beetle, or curculio, from Mr. J. M. Bristol, of Virgil, county of Lincoln, Ont., and that we were unable to determine it. We have since made it out to be a specimen of *Lixus concavus*, Say, who gives the State of Indiana as its locality, but says nothing as to its food or habits. It must now be included in our list of Canadian beetles, and we trust that, in time, its natural history may become fully known to us. It is half an inch long, exclusive of the snout, which is long and curved, of a shining black colour, except where obscured by a thick yellowish down, which easily rubs off on the exposed portions of the body. It is chiefly remarkable for the large hollow at the junction of the thorax and wing-covers, whence it derives its specific name of *concavus* (hollowed).

Toads in Gardens.—In a lecture on "Insect Enemies," lately delivered by Mr. Treat before the Vineland Agricultural and Horticultural Society, the usefulness of toads in gardens was forcibly pointed out. The lecturer advised his hearers to carry all the toads they find into the garden, as they devour immense quantities of insects. A toad will swallow the largest specimen of a tomato worm, although sometimes he will have a hard time of it.

Transformations of Insects.—It is commonly and correctly said that there are four stages in the life of every insect: 1st, the egg; 2nd, the larva; 3rd, the pupa, and 4th, the perfect or imago state. In most insects the dividing line between these stages is well marked, the larva and imago being active locomotive creatures, capable both of eating and discharging fæces; and the pupa lying still all the time and neither eating nor discharging fæces. But in certain great groups, for instance the true Bugs and the Grasshoppers, the pupa is as active and locomotive and ravenous as either the larva or the imago, and sometimes cannot be readily distinguished by the inexperienced either from the former or the latter.—*Am. Entomologist.*

Entomological Annual for 1868.—It is proposed, should sufficient encouragement be given, to publish a Year Book of Progress in American Entomology, to be edited by Dr. A. S. Packard, Jr. Dr. J. L. Le Conte will contribute a chapter on the *Coleoptera*; Mr. S. H. Scudder, chapters on the Butterflies and *Orthoptera;* Baron R. Osten Sacken, a chapter on the *Diptera;* Mr. P. R. Uhler, a chapter on the *Hemiptera* and *Neuroptera*, and the Editor expects to receive aid from other entomologists. It is hoped it will prove a useful hand-book to every one interested in the study of insects. It will be published in 12mo size in the spring of 1869. An edition of five hundred will be printed, provided three hundred names can be secured. Will all entomologists desirous of aiding in the publication of such an annual send in their subscriptions in advance, that the means of publishing such a useful book may be afforded at the outset? Subscriptions, seventy-five cents a copy, received by W. S. West, Peabody Academy of Science, Salem, Mass.

Correspondence.

Emigration, and Hints to Emigrants.

To the Editor.

Many are deterred from emigration to Canada by the ridiculous ideas of our wooden country that have been so generally in vogue in Great Britain. Tales of our biting winters, our endless droughts, and interminable and impenetrable forests, are constantly going the rounds of English periodicals, and are eagerly drunk in by a multitude who delight in perusing the black side of the picture, rather than in sifting the probabilities and applying themselves to the work of ascertaining the true state of affairs, or discarding the exaggerations of the traveller, who, by adding fresh horrors to his tale, hopes to increase his prestige as a *voyageur*. We constantly see articles and correspondence in the public journals advocating immigration, and decrying the action of the respective Governments for their dilatory legislation on this subject. Such statements unfortunately stand upon good foundations; but let us remember that the Legislature is but a cumbrous machine, oiled and run by many engineers, each of whom brings different ideas to bear upon the improvement of the power. There is a way in which we may individually do a great deal to further the cause of immigration. Many, doubtless, of your readers, come from parts of the old, world in which, even after a long absence they are well remembered and respected. If such would make a special point of writing to their old homes, publishing such correspondence in the local newspapers, and set down in plain terms the advantages held out by Canada to the emigrant—the exact state of affairs here—and confute the exaggerated yarns of those whose only object in writing has been to appear great travellers, they would do much to further the cause of immigration, and to help the Government in any steps they might take in the same direction. Depend upon it, the ungarbled accounts of the actual settler, known personally to many of those whom he addresses, and with the evidence of his own prosperity to back his statements, would do more to turn hitherward the tide of emigration than the most elaborate policy of the wisest Government. The course suggested would be mutually advantageous to the struggling classes in the old country and to ourselves. The cry is constantly coming up for more hands, and a better regulation of wages. Every immigrant strengthens the hands of the farmer, regulates the tariff of wages, and is, in the words of a great American statesman, "worth five hundred dollars to the country." Allow me, through your columns, to make a few remarks on this important subject, and briefly to notice several classes of emigrants, throwing out a few hints for their guidance in this country.

First—The farm labourer. Secondly—The emigrant to the back woods. Thirdly—The old country farmer as an emigrant, and fourthly—The emigrant with a limited Capital.

The Farm Labourer arriving at the port or place from which he proposes to start, should at once apply to the emigrant agency, finding out who may have notified their want of such services as he can fulfil, apply and settle, upon a place of service as soon as possible. The man unacquainted with the *modus operandi* of this country cannot expect high wages at first—he must undergo his probation. But he should hardly accept as a farm labourer less than $8 per month in winter and $12 per month in summer, with his board and lodging, allowing that he be a steady, able-bodied man. He must be prepared to discard many old country fashions. At home, where labour is abundant, every man is employed in some special capacity—as ploughman, as cattle feeder, as hedger, &c., but here we require our farm servant to turn his hand to anything and everything according as the seasons change. You are not an efficient farm servant unless you can put your hand to the plough, reap and bind in harvest, chop wood and attend to stock in winter—in fact, be willing and able to take up any job that may be placed in your hands. Devote yourself earnestly to acquire the art of chopping, for that is a necessary work for any Canadian farmer or his man. There is no difficulty in chopping, if you will take the advice that may be tendered by your fellow axemen. If you arrive in winter, and are placed in charge of stock, remember that to do justice to yourself and your charge there are certain essentials that should be carefully borne in mind, namely, warmth, regularity of feeding both as to time and quantity, and, above all kindness. Follow these, and the looks of your charge in spring will be your best recommendation to an increased wage or to a new master. Beware of whiskey, which is the curse of Canada. Not only is the mere habit of intemperance a stumbling-block in the way of progression, and a high road to ruin here and hereafter; but the greater part of the liquor dignified by the name of spirits is here simply an actual poison. Companions, either good or bad, are more easily formed here than in the old country. Men meet more freely, and, owing to there being less restraint upon the intermixture of classes, acquaintances are very much more quickly formed. In a land of strangers, removed from the circle of those with whom probably you and your forefathers have for generations borne a good character, and whose opinion hitherto kept you out of bad company—if you have not made up your mind to work steadily and with perseverance, you have been mad to expend your hard earnings in taking a passage to this country. You have made a fearful step in life, and you can expect no help in a land whose people know naught about you. Look forward, and bear in mind that many of your class have come to this land with an empty pocket, and are now the owners of fine farms, saleable at any moment for $5,000 or $6,000, with a family of educated children around them, and a home made by themselves, the reward of an honest perseverance and an upright course of life.

The Emigrant to the Backwoods. I would advise the man whose intention it is to carve out a home in the backwoods of Canada to spend some time, even if he gets but small recompense for his labour, in the family of a Canadian, to fit himself for the peculiar work and learn to adapt himself to the ways and wants of the life of a backwoodsman. Indeed, a man, be he ever so strong, persevering, and willing to work, can hardly expect to surmount the difficulties to be encountered in a bush life without first obtaining a thorough insight into the ways and means of subduing the forest. By all means, he must become an expert in the swing of the axe, and understand the mysteries of logging, burning, fencing, and then cultivating the rough surface of the hitherto unbroken soil, and make himself sufficiently acquainted with the wants of the settler, shut out from communion with his neighbours for a long time by impracticable roads or deep snowdrifts, so that he may not be surprised inadequately supplied with the necessaries of life. If the emigrant, however, has determined to proceed straight to the interior, the following hints may be of some service to him: Provide more than one good axe. Do not buy poor axes because cheap. Get them from such a maker as Hourigan of Dundas or Henderson of Galt. Take a good grindstone, and bestow upon it great care, keeping it free from grease, and rounded off on the grinding surface. The clothing best adapted for our winters in the woods consists of woollen homespun, such being more durable, warmer and cheaper, than any cloth. For provisions, a good stock of cured pork and a supply of oatmeal and flour, are essentials, and it would be better not to forget to lay in a supply of groceries, &c., before proceeding to a part of the country where dealers in such goods are few and far between.

Provided with good axes and a few generally useful tools, clothing of homespun, a supply of pork, oatmeal and flour, a log shanty to cover your head, a good yoke of oxen, and above all, a stout heart, the backwoods settler may soon transform the howling wilderness into a blooming garden.

The Old Country Farmer as an Emigrant.—There are many tenant farmers in the old country, who under the rule of a harsh landlord or his tyrannical agent, would eagerly grasp any opportunity of emigration that might arise. To such I would say—as to members of, perhaps, the most prejudiced class in Great Britain—remember that there is a great difference between farming in Canada and in the old country. Throw aside your prejudices, and weigh carefully the merits of our system of farming as applied to our own climate and state of progression, and beware how you make light of advice given you by Canadians. I speak advisedly, for I know how Englishmen are apt to regard colonial efforts. Here labour is scarce and wages high. You cannot employ your time to advantage, as has been your custom, in riding around your farms overlooking the workmen. Here you must turn in yourselves and show your men by example how to work.

The Emigrant with Limited Capital.—A little capital will go a long way in this country, if judiciously invested. The frequent failure of this class of emigrants heretofore has caused many to assert that a man had far better sink his capital in the ocean, or at least leave it locked up at home, and commence life here moneyless.

It is true that a great many that have landed in Canada with a certain amount of capital, have found that the small stock of cash which they may posses here, goes so much further than an equal amount at home, that they have justified themselves in a rush into extravagance, had their fling, and sunk into an obscurity from which they seldom arise. But this will not be the plan adopted by men of sense. Invest a portion of your capital in a suitable farm, stock it thoroughly, for no farm will pay unless well stocked; but be careful that these outlays do not exhaust your treasury. I know of no business to which a working capital is more essential than to that of the farmer.

Many of our farmers are now working in Canada on a hand-to-mouth system, that has for years paralysed all their efforts at improvement. They must have a crop every year from all their farm to keep them going. They have not a cent in reserve, and cannot, therefore, give their soil rest, or the necessary manure. The wants of to-day debar the possibility of waiting for a crop, and if a bad year intervene, where are they? They have nothing upon which to fall back in that rainy day; they sink into a depth of debt from which it may take a lifetime to recover. Every day there are excellent chances cropping up to the immigrant with a small capital. There are plenty of farms thoroughly cleared, excellently situated, well provided with wood and water, which have become a drag upon the husbandman, who for years has constantly drawn upon his soil and deposited naught. These may be bought cheap. Let a man who has some capital invest in such a farm, holding back enough that he may not be driven to extremities by a bad season, and devote his time and attention, not to a futile attempt to surpass his neighbours' crops, but to the enrichment of his heretofore impoverished lands, and the general improvement of his farm. Rest assured there is in Canada no better or safer investment for capital. I know of a farm that was bought in the township of South Dumfries for $30 per acre. It was worn out. The purchaser was a man with some capital. After paying cash for and stocking his farm, he invested the residue in securities which brought him in about $300 per annum. For five years he devoted his time steadily to the

improvement of his farm. During the first three years the returns barely paid for the labour. In the fourth and fifth years manure and judicious cultivation began to tell. From that time he put by money yearly, and in the ninth year from the time of his first investment he sold the farm for $70 per acre. Suit your acreage to your purse, and be sure in buying and stocking to leave a large margin upon which to fall back, if crops should at any time force you to wait.

C. E. W.

Notes and Comments.

To the Editor.

SIR,—It is much to be regretted that your valuable journal does not find its way into every farmer's house in Canada. It is not, however, the trifling amount of the annual subscription which excludes your journal from many homes in which it is urgently needed, so much as a contemptible prejudice entertained by short-sighted and crotchetty farmers, who affect to scorn all information which has not been acquired by themselves or their ancestors in the dear school of experience. When men are above being indebted to printer's ink, or their neighbours, for new ideas, it is not surprising that so many should go to the wall. It is astonishing that such a spirit should prevail, and that the improvements and progress which men of broader views are making do not arouse others to enquire and investigate—to go and do likewise.

I was much interested in some of the contents of your January number. It is certainly very encouraging to learn, as we are told in the first article, that Mr. Johnson's "half-rotted sod" produced eight hundred bushels per acre! Most of us, I opine, would be thankful for such a return after a liberal dose of barn-yard manure, supplemented without stint by the usual "artificials."

I was on the point of writing to you for information as to the expediency of winter fattening sheep, instead of oxen, when I noticed the letter of J. M. Do you not think, however, that well saved straw and a few roots would be cheaper than, and yet as good food as clover hay alone, and that access to unsullied snow is a sufficient substitute for water? In this neighbourhood few sheep get anything else in winter wherewith to quench their thirst. In deciding upon the relative advantages of feeding sheep and oxen, it should be remembered that sheep require much less attendance and much less expensive shelter than horned cattle. As none of my neighbours have had any experience in the matter, I shall feel obliged if some one who has will inform me, through your columns, which class of stock he considers the more profitable to winter feed, all things taken into account.

"X. Y. Z." has furnished you with a communication extolling the "dignity of agriculture." I do not intend to call it in question. When the circumstances of the farmer do not impose on him (as, unfortunately, they too often do) the necessity for such a large amount of physical labour as to render him unfit for much systematic thinking, his occupation calls, or should call, into play more of the powers of the mind than any other under the sun. Besides which, he needs, and often exercises, more manual skill than any artisan. The pleasures and advantages which the farmer enjoys are numerous, real, and lasting. They are often dilated upon, and I need not refer to them now. But in fairness it should be remarked that the calling is not without its disadvantages, especially in a new country, and in a climate such as ours. It certainly should not be chosen by a person whose gregarious instincts are very strong. Detained at home by press of work in summer, and blocked in by snow drifts in winter, he becomes shy and taciturn; and when, once in a while, he does go into "society," he is, however well informed he may be, totally eclipsed by the "dry goods clerk," who occasionally condescends to display his material wealth (which is all upon his back), and his brain power (which find its way to his tongue with wonderful facility) at a party in the country.

These drawbacks are, however, small, in comparison with the solid advantages of the farmer's calling.

Selection of Judges and Officers of Agricultural Societies.

To the Editor.

SIR,—The letter of your correspondent on the "Judgments at Poultry Shows," will bring to the minds of your readers many similar instances of their own personal experience, showing the total want of capacity in many of the judges appointed by our Agricultural Societies, in every class. This arises mainly from the negligence of the Directors of the Societies in not appointing men practically conversant with the duties pertaining to the responsible position of judges at our shows. Much, we know, may be said as to the difficulty of obtaining suitable and capable persons to officiate as judges, who do not themselves compete in the different classes; and also of the lack, in some sections, of men who are properly qualified to act as judges in some particular classes, men, especially, having a knowledge of the points of improved animals. But this difficulty can be overcome, to a great extent, by the arrangement now practised in some counties, of exchanging judges with other societies, thus giving a wider range for selecting men properly qualified.

But, to commence at the beginning of things, our Agricultural Societies, to come up to any fair standard, must give more attention to the selection of their officers. What would be thought of a medical society composed of farmers in general, small lawyers, and grocers? Yet such is the very system worked upon by some "Agricultural" Societies. I know of a Society, whose list of officers, for years, was made up on this principle. Every broken-down merchant and political hack, in a wide extent of country, seemed to be represented in the list of officers of that Society. The result was that the Society's funds were frittered away in ridiculously small premiums, and nobody knew where. Nobody took pains to bring into the county any of the improved breeds of stock, and, as a consequence, the agriculture of that section is an age behind the time. The Society had done nothing towards the creation of a taste for better breeds of stock, and little for the improvement of husbandry in general.

But a change has come over the spirit of their dreams, and the Society has this year at its head an energetic, thorough farmer, with a practical understanding of the requirements of our agriculture, and it is the intention of the officers to agitate the question of devoting the funds of the Society for the importation of a horse for the use of the members; and we may yet see an improvement in the agriculture of the district as rapid in progress as it was slow and backward before.

When members of Agricultural Societies see to electing efficient and capable officers to preside over their affairs, we shall find little cause to complain of the selection of judges to determine and award the prizes, and less in the management of the Societies in general. There is certainly great room for improvement in many Societies in these respects.

W. Y. Z.

Ontario, Canada, February, 1869.

Keeping Ice.

To the Editor.

SIR,—In your issue of 15th February, page 76, I find an article entitled "Preserving Ice," by J. M., in which the writer details the *modus operandi* of preserving ice and building ice-houses. It is not my purpose in this note to enter into any details about buildings fitted to keep ice, but simply to state a few facts, which can be fully substantiated, showing that ice may be kept for several years in any sort of house or shed, provided the ice is well packed around with sawdust. There is to be seen at this date (February 22nd) ice three years old, being the crop of 1866-7, at the residence of Hon. D. L. Macpherson, Chestnut Park, which ice is as sound and good as when first put in; not that age in ice is any advantage, but this goes to show what can be done towards its preservation.

I will briefly describe the whole secret, trusting it may be of some service to dairymen and others, to whom a good supply of ice in summer is important. The house, or rather shed, is of wood, 12 by 14 feet inside measure. It was excavated about 14 inches below the surrounding surface, this space being filled up, or nearly so, with pine saw-

dust, upon which are built the blocks of ice to the required height, filling in all openings carefully with small broken pieces, and leaving all round the outside a space of about ten inches, which is filled up with sawdust and pressed down with the foot, as each alternate tier of ice is built up, with about the same thickness of sawdust spread over the top when the house is filled. There are two Louvre board ventilators one at each end, near the roof, which are always open to admit air, besides a chimney-shaped ventilator over the roof, also open night and day.

The great secret, I hold, is in the sawdust being a non-conductor, and not in the house itself nor its situation. The house here spoken of stands facing the south, fully exposed to the sun the greater part of the day. Straw of any kind I consider a complete nuisance, as it soon rots, whereas the sawdust may be used for a number of years. The only precaution necessary is to see that when any ice is removed, the exposed part is covered up again, and all will be right. Finally, I would say to one and all who wish to keep ice for years, try the sawdust.

Chestnut Park. G. VAIR.

NOTE BY EDITOR.—In the former article above alluded to, straw was recommended not as the best, but as the most easily procured material, always at hand on the farm, and it will answer the purpose nearly as well as sawdust for one season.

Commendatory.

To the Editor.

SIR,—I have read the first number of the CANADA FARMER for 1869, and cannot help making some remarks on the same. I have been a subscriber from the commencement of the paper, and well pleased with all the first series, but I consider the last an improvement on its predecessors, and think it strange the paper is not taken by every householder in the Dominion. I would especially call attention to three articles, which I consider of more than ordinary value. The first, in the stock department, on page 7, "on the Winter Management of Live Stock;" second, "the Culture of the Apple," on page 11; and third, "Entomology," on page 30. I have had each volume nicely bound for 30 cents, and the volume of 1869, will make a more handsome book, as it will be more compact. I am well pleased with the former books, as it is impossible to open one of the five without finding something interesting on agricultural or horticultural pursuits. Had the same facilities been at my disposal in times past, I should now have quite a library. According to my judgment, the price being the same, I would without fear or favour choose the CANADA FARMER to-day in preference to any of the United States journals, excellent as many of those are.

PETER SHISLER.

Bertie, March 5, 1869.

Mr. Simon Beattie.

To the Editor.

SIR,—I see in the CANADA FARMER, Dec. 15, a proposal for getting up a testimonial of some kind to Mr. S. Beattie, for what he has done in the way of importing thorough-bred stock of various kinds into Canada. I believe he has done more in this way than any other single individual, and I am sure many like myself will be happy at having the opportunity thus offered of showing their obligation to Mr. Beattie, which they could not do in any other way.

But I owe Mr. Beattie a debt of gratitude of a different kind, which I have much pleasure in mentioning here. Two years ago my father, Alex. Kerr, of Westminster, who is since dead, in going to Mr. Snell's sale of stock, arrived at the Brampton station of the railway at 11 o'clock p.m., the night before the sale, and in stepping off the car to the platform, it being dark and ice on the steps, and the car still in motion, his foot slipped and he fell between the car and the platform, with his legs across one of the rails. The next moment he would either have been crushed to death or had both his legs taken off, when this Mr. Beattie, who happened to be near, at considerable risk to himself, took hold of my father and drew him up on the the platform, and thus saved his life. I know, if my father had been alive, he would have been happy at this proposal in honour of Mr. Beattie, and I shall be glad to have a small share in it as soon as the course is pointed out.

JOHN KERR.

The Canada Farmer.

TORONTO, CANADA, MARCH 15, 1869.

Agricultural Pursuits.

An evil against which we cannot too often and too clearly speak, is the tendency among the young men of our country to concentrate in our large towns and cities. The vulgar question of "How to make a living" is one which very naturally presents itself to young men at the threshold of life, at the point where they find themselves confronted with the realities of life, and have to fight its battles. With many, it is simply a question of living—of providing food and clothing; with others, who have little fear on this point, it is a question also of how to get on, so as to make their mark in their day and generation. With the former, it is a matter of necessity; with the latter, one partly of necessity and partly of ambition. Both classes, however, have to face the subject of their future calling or avocation; and as the matter affects both themselves and succeeding generations it is a most important one.

The occupations of a city life are admittedly very different from those of a country one, and there are special advantages appertaining to each. We do not complain of men who have special aptitude for commercial, banking, speculating, or other such pursuits betaking themselves to their proper specialty. That is not only becoming, but in most cases essential to success, and generally advantageous to the country. As a rule, no man should go into a business for which he is not fitted and has no special liking. The trouble is that, in too many cases, men will try what they are unfitted for, and consequently fail of success. In this country, a noticeable tendency—as we have intimated—is that of men whose fatherf were farmers seeking to displace the paternal avocation with something—as they suppose—more genteel and more profitable.

Now, we hold it to be a matter for congratulation that we have a fine agricultural country. We have broad and fertile acres, and many of them. As compared with the British Isles, the extent of our country can only be properly characterised by the school-boy's superlative degree, especially if we count in the vast and fertile regions of the Red River and Saskatchewan valleys. No country—other things being equal—could possibly fail to compete advantageously in the race of life, which has a large agricultural population. Cicero said so, and he had far weaker reasons than we could adduce, for the assertion. Our main dependence must be on our agricultural resources, and on the stout hearts and brawny arms that develope them. The pursuit of agriculture, therefore, must with us ever be an honourable and profitable calling, because it is the mainstay of the country, and success lies in its path.

Holding these views, we cannot admit it to be wise or politic for country lads to be sighing after city life. Cities and towns will only bear a certain number advantageously, and when that number is exceeded, the result is most disastrous to young aspirants for "situations," or for "genteel" avocations. It is notorious that the legal and medical professions are becoming overcrowded. In this very city there are many belonging to these professions who can barely make ends meet, and not a few, we fear, who cannot be said to do even that. In some cases this is, perhaps, attributable to want of ability and tact; but the great cause is, undoubtedly, the number who enter those callings. Young men on the farm sigh to themselves—"be not like dumb driven cattle; be a hero in the strife,"—and the inspiration drives them to aim at what they are probably un-

suited for. The daily routine of toil is tiresome. The rewards, though sure, are somewhat slow, and lack the zest and excitement which, it is supposed, accompany other pursuits. And it must be said, too, that many parents are at fault in this matter. They encourage their sons in this idea. Some well-to-do farmers, forgetting or ignoring the safe road by which they attained to competency, look upwards, and seek the luxury of seeing their sons dubbed Rev., M.D. or Barrister-at-Law; or, failing in that, aim at seeing them in neat attire and with soft white hands, counting out money over the Banker's table, or exhibiting to dashing young ladies the latest fashions in dress.

The whole thing is wrong. Farming is not only a useful, important and honourable calling, but it is also a sure and profitable one. There is ample and ready market for all that is produced, and the business is attended by comparatively very few risks. All that is needed, in order to secure competency or even independence, is energy and industry. The farmer is one of the least dependent of men. He is little in danger from the quicksands of trade, the rascalities or whims of men, or the general uncertainties appertaining to the busy marts where scheming and smartness are in full play. Contrast with this the position of the clerk. He is at the mercy of his employer, and may have to be humbly seeking employment several times in a single year, and be glad to get it where he can at from $6 to $10 a week. He lives from hand to mouth, and if, besides saving nothing, he is not preparing the way for business on his own account, he is simply dooming himself to a life of abject dependence, if not sycophancy, and loses all manly self-reliance. John Stuart Mill tells us of the regret he experiences whenever he sees a well-built, brawny fellow dealing needles and laces and trinkets over the retail counter. And admitting that there must be many exceptions in practical life to any theoretical view dictated by the fitness of things, we may well ask, would it not be better—would it not, in many cases, comport better with the manhood of man—to go boldly into our back country and work up a safe and independent business there, than be whining helplessly in crowded cities, jostling among the throng that rush for every "vacancy," or earning but a scanty and precarious livelihood? The prizes in commercial or professional life are attained by but a few, and only those should look in that way who have special capacity, or whom special circumstances favour.

Canada must rely in the main upon her agricultural population, and while there is such ample room, we hope to see our farmers and their sons and their sons' sons apply themselves vigorously to the farming business. The question of immigration is forcing itself more and more upon the attention of public men, both in this country and in Britain, and we are glad it is so; but its main use will be, while relieving the old country of a surplus population, to plant upon our soil a sturdy class of men, to cultivate and utilise our wild lands—men who will not fear honest labour, and who will be the mainstay of the country in peace or in war. Happily we have a country eminently fitted for just such a class of men. Canada proper contains any amount of forest land, and in a short time we shall also have the immense prairie land of the Red River Territory. We shall thus be in a position to offer the immigrant his choice. The Western States have hitherto proved a wonderful attraction to immigrants, and the reason was undoubtedly their prairie land. Most new-comers have but limited means, and can ill afford to spend two or three years in clearing the forest before reaping the reward of their labour. A prairie region admits of immediate returns. The North-West Territory affords all the advantages of the Western States in this respect; and, we doubt not, will ere long, under the wing of the Dominion, attract a large proportion of the stream of immigration from the old country. That is the field for our able-bodied, industrious young men. If they deem the paternal estate too limited or dread going further back into "the bush," let them go to those western prairies, and not to our already overcrowded cities.

Report of the Commissioner of Agriculture and Arts, of the Province of Ontario, for the year 1868.

We have received the first annual report which has been issued from the present Bureau of Agriculture. It has been brought out under the disadvantages inseparable from the first year's operations of a new organization, and of unavoidable incompleteness of arrangements in various departments; but contains, nevertheless, much valuable information, and gives promise of efficient management in the future. The publication makes a thick octavo volume, comprising altogether 272 pages. The report proper is very brief, and adverts to the constitution of the Bureau, the main features of the new Agricultural Bill, and the official operations of the year, which have been necessarily initiatory and to a certain extent experimental. The bulk of the volume is made up of various appendices, of which the first is a catalogue of the library. This is open to the public, and already contains many valuable books, and will in time, it is hoped, be so largely augmented as to become an institution worthy of the Province.

Next follows a very interesting report of Professor Buckland's visit to England, giving an account, among other things, of the Royal Society's Show and other important agricultural exhibitions. There is much in this part of the report that should be suggestive and instructive to Canadians. In particular we would commend the admirable management by which all crowding, confusion and hurry are avoided. This result is mainly secured by allowing plenty of time both in the preliminary arrangements, and for the main object of public inspection. All entries are strictly closed by a certain date, prior to the opening of the exhibition, and ample space and commodation are provided for visitors as well as for stock and implements. An important feature is the trial of implements previous to the award of any prizes. These trials in connection with the Royal Society's show occupied a week, although the competition was confined to implements used in cultivation. Those employed in the subsequent operations of harvesting, threshing and preparing for market, will be tested at the Exhibitions of 1869 and 1870. Much attention was given to steam cultivation, which is yearly gaining ground in Britain, and will doubtless ere long be employed in most of the important operations of the farm. The recent progress in agricultural mechanics generally, has been well illustrated in the history of the Royal Society's Exhibitions. At the first show in 1839, there were only 20 exhibitors of implements; at the Leicester meeting in 1868, the number of exhibitors was 307, occupying 337 stalls, comprising 6,369 articles under a shed 16,700 feet in length, and covered by nearly 50,000 yards of canvas. A very large proportion of these implements are of quite recent invention. The same excellence and progress were manifest in other departments, especially in the show of stock.

We are convinced that in this country, to make our exhibitions practically valuable, more time must be allowed. We agree also with the Commissioner's suggestion, that in many instances an amalgamation of the smaller shows with the larger, so as to diminish their number, and at the same time raise their standard of excellence, would be attended with signal benefit.

Professor Buckland's report goes on to speak of the important matter of the introduction of fresh seed, one of the chief objects of his visit to England; and on this subject he gives some judicious cautions respecting the necessity of careful experiments before investing largely in such ventures, as the difference of climate and other causes sometimes lead to very discouraging results. The importation of seed wheat from Russia, in particular, should be intrusted to a reliable agent in that country, for much of the wheat exported thence is kiln-dried and totally unfit for seed, besides consisting of a mixture of different varieties.

Some arrangments have been made, we are informed, for obtaining specimens of British agricultural implements, and the Messrs. Howard, of Bedford, very liberally granted the loan of a number of their implements for the Agricultural Museum of this Province. The British manufacturers complain very naturally of the high import duties levied on their machinery here, and which no doubt keeps out of this country many most valuable implements, which under a more generous system of legislation would be available to Canadian farmers.

Professor Buckland's report, after adverting to arrangements made by him for the interchange of reports with British Agricultural Societies, closes with some judicious remarks on the subject of emigration, which is now attracting so much attention in Great Britain. He deprecates, as we do most strongly, the introduction into this country of the refuse population of English cities, and the incapable or vicious portion of the pauper burden of the old country For suitable classes of emigrants, however, there are here ample room and great inducements. We most earnestly hope that the Government of Canada will give this subject that careful attention which the present crisis especially and most urgently demands.

An analysis of the reports of Agricultural Societies throughout the Province comes next in the contents of the volume under notice. These accounts are almost entirely confined to financial statements. We are glad to learn that printed forms have been prepared for these reports in future, which will secure fuller information and greater uniformity for the purposes of comparison and analysis.

Next follows a summary of crop returns from various societies; but these, on account of the short notice given, and other causes, are very incomplete. Some more efficient system than any hitherto adopted must be put in practice before we can obtain any general and reliable statistics on this important matter.

Statements and abstracts in reference to Mechanics' Institutes come next in order. A fresh impetus has been given to these useful institutions by recent legislation, and the assistance now offered under certain conditions by grants from the Government will no doubt largely increase their numbers and their efficiency.

The report of the Fruit Growers' Association, which follows, occupies considerable space, and contains much valuable matter. Some of this has already been published in the pages of the CANADA FARMER, but much of it has not been made public in any shape. Of this class is a very valuable report by Mr. Saunders, on fruits in the neighbourhood of London, with interesting notices of a great number of injurious insects. It would be very desirable if these transactions and papers could be printed separately and distributed among the members of the Association, and others interested in the important subjects of fruit-growing.

At the end of the volume is given, in the form of a supplement, a full account of the recent investigation into the financial position of the Board of Agriculture. This matter is now too well known to need any further comment. The facts of the case amply vindicate the course adopted by the Commissioner of Agriculture, and show that he has acted throughout in a manner that entitles him to the thanks of the community. We trust that the new Council of the Agricultural Association will wisely exercise the powers entrusted to them, and that the next report of the Commissioner of Agriculture will show material progress in the most important interest of the country, and the basis of our national prosperity.

The Emigration Question.

There is considerable discussion going on just now in the columns of the press, and among the public in general, as to how we are to obtain some increase to our labouring population, and divert to our country a portion of the tide of emigration, setting in a steady stream from the older countries of Europe to the shores of America. The English journals are also taking up the question, and after showing that every working man in England "carries a pauper on his back," they very considerately, on philanthropical grounds, we presume, propose to relieve the pressure upon their workmen, and the parochial rates at the same time, by sending a few shiploads of paupers to Canada.

There can be no doubt of the fact, that we are greatly in need of steady and industrious labourers to work in the cultivation of newly opened lands, as well as to take the place of a large number of our young men, principally farmers' sons, who most unadvisedly, as we could show, have left the paternal home disgusted at the worse than do-nothing policy of the Canadian Government in the matter of Crown Lands, and gone to the Western States, where land could once be had cheap, and every encouragement is given to the settler in preference to the speculator. Many a farmer now plods wearily alone who once had grown up boys to assist him in his work, and would be but too glad to give a home and helping hand to a steady, industrious labourer, who would be willing to give a fair amount of work for a fair day's wage.

But it would be very unfortunate indeed for us, if under the seeming guise of a blessing, we should find, when too late, that we are receiving a curse, and instead of obtaining labourers to till our fields and help to gather in our bountiful harvests, we are unwittingly taking the weight of the pauper from the Englishman's back to carry it upon our own. To those who have seen the working of the system of parochial relief in England, and the class of persons too commonly supported on public charity, it will be no matter of surprise to learn, that for pig-headed, obstinate laziness, an English pauper stands unrivalled.

We have recently read many articles in the British Agricultural papers on the labour question, and from them we gather that all efforts to improve the condition of the agricultural labourer at home, are in a measure rendered nugatory by his own ignorant prejudices, and that while labour is seemingly cheap, it is found less costly to employ expensive machinery to do the work of the farm, wherever it is practicable to do so.

There is, however, an exception made in favour of the Scottish labourer, and we see it stated that the cost of working farms in Scotland is much less per acre than in England or Ireland, because while a Scotch labourer will obtain double the wages, he actually performs four times the amount of work that an Irish labourer does, and two men on a Scotch farm do all the work that it requires eight men in Ireland to perform. It is an old and true saying that "heaven helps those who try to help themselves;" and while we have no desire to add to our already too large stock of idlers, we could not go far wrong if we were to give a measure of assistance to such of the industrious poor at home as desire to better their condition by coming among us, and at the same time have some small means of their own—enough to place them above losing self-reliance—yet perhaps not sufficient to enable them to come across the ocean with their families, without sacrificing their little all in the effort to reach their new home, and finding themselves in the humiliating position of being obliged to suffer from want, or be treated as beggars. These are the class of persons that we can encourage to emigrate to our shores with a reasonable prospect of their becoming useful to us at the present, and a credit to themselves and their adopted country in the future. They would require to be shown the advantage that would accrue from their taking the step, without, at the same time, being misled by overdrawn accounts of high wages, &c., and to have some direction from a properly qualified agent, who should also arrange all matters of transit for them, and we should have homes ready to receive them on

arrival at their destination. This is substantially the plan pursued by the Australian Colonies to obtain the bulk of the labourers and artizans required to carry out works of public utility, and help to bring under cultivation the agricultural lands, which were sold by the crown to actual settlers only, at £1 per acre; the proceeds to be devoted for a certain time to the encouragement of immigration. They employed well-paid agents at British ports, men of honour and ability, who were careful to see that none but persons of the right stamp were sent out. Half the passage money was paid by the agent, the balance by the passenger. Some such scheme of assisted emigration would be well adapted to the present wants and condition of Canada, and in this way the Government might most profitably expend a portion of the public money.

Notes on the Weather.

February has been colder on the average than January, but is warmer than the average of several years past. There has been an abundance of snow, more than enough and considerably drifted, so that travel is rather impeded than helped. There have been 11 clear days, 17 cloudy days, 14 days on which snow or rain fell. The highest temperature was 49° on the 12th, the lowest 0° on the 27th, the prevailing winds W. and W. S. W. The ground is now covered with snow to an average depth of two feet, and the prospect is that March will prove cold, and spring come in with a sudden and rapid thaw, and as the frost has not penetrated deeply into the soil, we may look for an early and favourable spring.

REGISTER OF RURAL AFFAIRS.—We have just received a copy of this favourite annual, published by L. Tucker & Son, of Albany, N.Y., the proprietors of that sterling agricultural journal the *Country Gentleman*. It is the most perfect thing of the kind yet got up, and we wonder how they can afford to give such a neat volume of 336 pages, with 130 engravings, for so small a sum as 30 cents. We have only had time to glance through its pages. The first article, on the "Culture of Wheat," is alone worth double the price of the book, and the next, on the "Management of Hedges," is good and practical. Then there is "Culture of the Potato," "Rural Improvements," "Strawberry Marketing," "Grape Houses," "Packing Grapes for Market," and about thirty other articles on various subjects pertaining to the farm, garden and household, any one of which is worth the price of the book.

In England many farmers support large families on the produce of six English acres of land, besides paying heavy taxes. Many in Germany do even better than this.

Horticulture.

EDITOR—D. W. BEADLE,
CORRESPONDING MEMBER OF THE ROYAL HORTICULURAL SOCIETY, ENGLAND.

General Meeting of the Fruit Growers' Association of Canada.

HELD AT HAMILTON ON THURSDAY, THE FOURTH DAY OF FEBRUARY.

The meeting was called to order a few minutes after ten o'clock, a.m., the President, W. H. Mills, Esq., in the chair. There was a very good attendance of members, several from Toronto, London, Paris, St. Catharines, Cayuga, and Niagara, being present

The minutes of the last meeting, which was held at St. Catharines, were read and approved. The President read a short address touching several matters affecting the interests of the Association, and congratulating the members upon the progress already made, and particularly upon the very valuable and instructive character of the report.

On motion of Mr. John Gray, seconded by Mr. George Leslie, Jr., it was resolved

"That Horticultural and County or Electoral Division Agricultural Societies be allowed to affiliate with this Association on payment of two dollars annually, and be allowed to send two delegates to each meeting, and be entitled to two copies of the report of the transactions of this Association."

On motion of Rev. Mr. Burnet, seconded by J. C. Rykert, Esq., it was resolved

"That the Secretary be directed to keep *in retentis* the record of remarks on subjects for discussion at the meetings of the Association, and that he simply enter in the minute book the acts accomplished."

The meeting took up the list of Pears, and proceeded to discuss the merits of the several varieties, with a view to the revision of the list.

BARTLETT; Mr. Burnet, of Hamilton, thought it hardly sufficiently hardy, and would suggest that the *Annanas d'Ete* be cultivated in its place.

Mr. D. Murray, of Hamilton, believed it to do very well about Hamilton, and said it was early, very valuable, and quite as hardy as any other, both on the pear and the quince stock.

Mr. Ball, of Niagara, found it sufficiently hardy, and that if plucked when half grown, and put away in the house, it would ripen well.

ANNANAS D'ETE; Mr. Burnet said it ripened about a week later than the Bartlett, was a superior pear, does not rot at the core. will keep for a considerable length of time, and is a good market pear.

Mr. Leslie, of Toronto, has had better specimens of this variety than of the Bartlett; it is a first class pear, thrifty grower, good bearer, and will stand the climate better than the Bartlett.

Mr. Gray, Toronto, said it was a better pear than the Bartlett, and considered it one of the finest early pears; could not speak of its keeping qualities.

BEURRE GIFFARD; Mr. Leslie, Toronto, thought this the finest early pear, most delicious flavour; has it as a dwarf tree, and it came into bearing at three years of age.

Mr. Gray, Toronto, said this was one of the very best of the early kinds, ripening before the Bartlett; the fruit is of medium size.

Mr. Holton, Hamilton, considered this a fine early pear, ripening two weeks after the Madelaine; it was a very spreading, ugly, slender growing tree, and required very severe pruning.

W. H. Mills, Hamilton, remarked that this was a good pear, of good flavour, a thrifty grower, and bearing young; he had had it as a standard four years, growing in a gravelly loam soil; it was very hardy.

BELLE LUCRATIVE; Mr, Gray—This is the best pear grown. Mr. Ball—Is a good bearer and grower, and an excellent eating pear. Mr. Mills—It is one of the best. Mr. Burnet—In August, when the winds are high, the long stalk of the fruit is apt to break, and the fruit fall to the ground. It should be grown in a well sheltered position. Mr. Holton—For dwarf culture it is one of the best; is a good permanent pear on the quince; it is a rapid grower, as good as Louise Bonne de Jersey.

BEURRE BOSC—Mr. Burnet said that if pruned in the fall the wood suffered from the winter; it was a good pear to eat, but the tree backward in bearing. Mr. Leslie—It stands and bears well in Toronto; quite hardy there, specimens not large. Dr. Cross said it grow well with him at St. Catharines Mr. Holton had very little experience with it; it blights with him; had a tree in his grounds for eight years; then it blighted and died. Mr. Beadle thought it quite tender in the north; it is one of the best pears grown, ripens in October, does not come into bearing as young as the Bartlett, will bear at five and six years. Mr. Freed said it was not desirable as a dwarf, did best as a standard, is a good pear. Mr. Arnold had it on trial at Paris many years, but did not succeed with it.

BEURRE SUPERFIN; Mr. Leslie said it was very much like the Beurre Diel, that he could not say much about it. Mr. Freed thinks it a good pear; has tried it, found it not very sweet; a good keeper, had them until the week before Christmas, quality variable. Mr. Burnet—It is a good pear, like Belle Lucrative in shape and colour; tree tender.

BEURRE CLAIRGEAU; Mr. Springer, of Hamilton, has fruited it for one year; it is a good pear. Mr. Saunders, of London—It is of good size and appearance; have grown it only a short time. Mr. Leslie—It is very tender, dies out very rapidly. Mr. Burnet—It is a good market pear, very showy but coarse-grained, ripens end of October.

BEURRE GOUBAULT; Mr. Gray would not grow it; it is very gritty. Mr. Saunders—Have fruited it, is finer than the Buffam, ripens with the Bartlett. Mr. Holton thinks the flavour not good; it ripens with the Buffam, not worth cultivating, not very early, and comes at a time when there are plenty of better pears.

BEURRE D'AMANLIS; Mr. Gray thought this a very good pear, requires to be severely pruned, medium sized fruit, ripens early in September, tree hardy. Mr. Leslie said that it is a very early bearer, quality medium, fruit showy. Mr. Burnet said the tree was quite hardy; he had not yet fruited it. Mr. Holton said it was much like Beurre Diel. Mr. Freed—The flavour is only middling.

BEURRE D'AREMBERG; Mr. N. Hamilton, Paris, thinks this well worthy of cultivation. hardy tree, good grower. very fine fruit, ripens late in the fall or early in winter, of a vinous flavour, very fair size, larger than Belle Lucrative. Mr. Ball—It is a good Christmas pear, a heavy cropper, fruit requires thinning out. Dr. Cross said it was a hardy late pear. Mr. Smith, of Grimsby, said the fruit was liable to crack, but it was a good pear, the tree a slow grower. Mr. Gray had given up cultivating it; the fruit was very gritty, he would not recommend it. Mr. Murray said it was very coarse and gritty, and ripened late. Mr. Beadle has cultivated it for twenty years, but only as a standard: is very productive, and apt to overload with fruit, so that the pears are small. Has seen it on the quince, where, when well cultivated and thinned out, it grows as large as the Bartlett. Some years it is very good, of a juicy, vinous flavour.

BEURRE DIEL; Mr. Burnet—This variety is very apt to drop from the tree, is a good fruit, can keep until Christmas. Judge Logie—Best late autumn pear, very hardy, good grower. Mr. Holton—It inclines to be gritty, a good bearer, do not call it a good pear. Mr. Freed—Does not think it of very good quality, is a good bearer, and will keep till Christmas. Mr. Beadle—Esteemed it one of the best of the season; quality is variable, and in no way to be compared to the White Doyenne; the tree is hardy, thrifty, and a good bearer; the fruit is always of good size and fine appearance. Mr. Leslie—It grows well at Toronto.

BEURRE D'ANJOU; Mr. Burnet has fruited it many years; is very handsome in appearance, of good flavour, and the tree bears early. Mr. Arnold—It is a very fine pear, ripe in November, a good keeper. Mr. Leslie said it did well at Toronto, a good keeper; tree bore at three years after planting. Mr. Gray had found it slow in coming into bearing, but thought it a good pear. Mr. Saunders had fruited it after four years planted. Mr. Freed preferred it to the Beurre Diel. Mr. Beadle was very much pleased with it.

BRANDYWINE; Mr. Burnet had fruited it; thought it first class, is a new pear, will keep only a short time; but when in prime is very fine; had gathered it on the 19th of September. Mr. Leslie has it in bearing, ripens early in September, poor keeper, tree hardy. Mr. Murray thought it a nice early fruit. Mr. Freed said it was a very handsome pear, but required to be eaten at the very moment it was ripe; would not recommend it. Mr. Beadle had fruited it four or five years; it bore enormous crops, was quite sweet and fine flavoured; the fruit would not keep; he would value the variety much if it should prove to be hardy.

BLOODGOOD; Mr. Arnold would strike it from the list as not worthy of cultivation. Mr. Holton agreed with him. Mr. Leslie said it was mealy and of no use.

BUFFAM; Mr. Leslie said it was a good pear, and should be grown on the pear stock. Mr. Arnold said it was well adapted to light soils. Mr. Holton said the tree was very ornamental. Mr. Burnet had found the fruit to crack on clay soil, though some years it was very good; the tree was inclined to blight. Mr. Beadle said it was one of the few varieties that were peculiarly adapted to sandy soils.

CATILLAC; Mr. Beadle said it was a large long-keeping pear, only fit for cooking. Mr. Burnet—it can only be used for cooking.

DEARBORN'S SEEDLING; Mr. Holton—Is a good bearer, but ripens too late, when there are plenty larger and finer. Mr. Burnet—A good cropper, fruit not stung by curculio; ripens in September. Mr. N. Hamilton, of Paris, thought it a very fine sweet pear.

DOYENNE D'ETE; Mr. Holton said it was the finest very early pear, quality very good, ripens two weeks earlier than Beurre Giffard, thrives best as a standard. Mr. Leslie—It is a good pear, earlier than the Madelaine, does well as a standard and on the quince stocks. Mr. Burnet considered it the finest early pear.

DOYENNE SIEULLE.—Mr. Gray—This is a very good winter pear. Mr. Leslie—Have kept it until Christmas, esteem it a very good variety.

DUCHESSE D'ANGOULEME; Mr. Burnet would rank this as first class. Mr. Martin thought none equal to it on clay soil. Mr. N. Hamilton had not found it to do well with him, though he had given the trees the best of care. Mr. Arnold said it was a fine large showy pear. Dr. Cross had noticed that the blossoms were easily blasted in the spring by unfavourable weather; the fruit was large and showy, but not of the best quality. Mr. Leslie thought very highly of it. Mr. Beadle thought the fruit of very poor quality.

EASTER BEURRE; Mr. Gray considered this one of the best of the season, comes early into bearing, would particularly recommend it. Mr. Murray—It is the best winter pear, keeps well into February. Mr. Burnet had kept it until May. Dr. Cross said it would keep until March, but did not value it. Mr. Arnold never saw one fit to eat, has kept them through the winter. Mr. Beadle has kept them until April, but did not think them worth much.

GLOUT MORCEAU; the testimony of nearly every one was to the effect that this variety is very subject to blight, though the fruit is of fine quality, and a great favourite with some.

A recess was ordered until half-past two. At that hour the President called the meeting to order, and appointed Messrs. Holton, Arnold, Hamilton, and George Leslie, Jr., a committee to examine the fruit on the table and report thereon.

It was resolved, in order to facilitate the business of the meeting, that a vote be taken on each of the several varieties yet remaining in the pear list, without discussion as to their merits, and that they be classified accordingly.

In this manner the pear list was finished, and the list of apples gone over, with the following result:

PEARS.

RECOMMENDED FOR GENERAL CULTIVATION.

1 Bartlett,	2 Belle Lucrative
3 Beurre Diel,	4 Buffam, on sandy soil,
5 Dearborn's Seedling,	6 Doyenne d'Eté,
7 Duchesse d'Angouleme,	8 Flemish Beauty,
9 Grey Doyenne,	10 Howell,
11 Louise Bonne de Jersey	12 Napoleon,
13 Pound Pear, for cooking,	14 Rostiezer,
	15 Seckel,
16 Sheldon,	17 Osband's Summer,
18 Swan's Orange,	19 Tyson,
20 Vicar of Winkfield,	21 White Doyenne,
22 Winter Nelis,	23 Windsor or Bell Pear.

PROMISING WELL.

1 Beurre d'Anjou,	2 Doyenne Sieulle.

FOR FURTHER TRIAL.

1 Annanas d'Eté,	2 Beurre Bosc,
3 Beurre Giffard,	4 Beurre Superfin,
5 Beurre Clairgeau,	6 Beurre d' Aremberg,
7 Brandywine,	8 Catillac,
9 Doyenne Boussoc,	10 Easter Beurre,
11 Figue d'Alengon,	12 Glout Morceau,
13 Golden Beurre,	14 Marie Louise,
15 Oswego Beurre,	16 Passe Colmar,
17 Soldat d'Esperin,	18 Urbaniste,
19 Washington,	20 Columbia,
21 Clapp's Favourite,	22 Edmonds,
23 Payency,	24 Bergamot d'Esperin
25 Archduke Charles,	26 Fulton,
27 Belle Williams,	28 Duchesse d'Hiver,

APPLES.

RECOMMENDED FOR GENERAL CULTIVATION.

1 Baldwin.	2 Duchess of Oldenburg
3 Early Harvest,	4 Early Strawberry,
5 Esopus Spitzenberg,	6 Fall Pippin,
7 Fall Jennetting,	8 Gravenstein,
9 Golden Russet of Western New York,	10 King of Tompkins Co.
	11 Maiden's Blush,
12 Northern Spy,	13 Pomme Grise,
14 Rambo,	15 Rhode Island Greening
16 Ribston Pippin,	17 Roxbury Russet,
18 Red Astrachan,	19 Sweet Bough,
20 St. Lawrence,	21 Swaar,
22 Snow Apple,	23 Talman Sweet
24 20 Ounce Apple or Cayuga Redstreak,	25 Wagner,
	26 Siberian Crab

FOR FURTHER TRIAL.

1 Alexander,	2 Bedeni,
3 Beauty of Kent,	4 Bourassa,
5 Colvert,	6 Canada Reinette,
7 Early Joe,	8 English Russet,
9 Golden Sweet,	10 Hawthornden,
11 Hewley,	12 Holland Pippin
13 Hubbardston Nonsuch,	14 Keswick Codlin
15 Lowell,	16 Lady Apple,
17 Newton Pippin,	18 Primate,
19 Peck's Pleasant,	20 Porter,
21 Pearmain,	22 Red Detroit,
23 Red Canada,	24 Seek-no-further,
25 Summer Rose,	26 Autumn Strawberry,
27 Swayzie Pomme Grise,	28 Tetofsky,
29 Vandevere,	30 Yellow Bellflower,
31 London,	32 Rome Beauty,
33 Domfule,	34 Barton,
35 Saxon,	36 Yellow Newton Pippin.

The committee appointed to examine the fruits upon the table reported that they found several seedling apples, shown by Ezekiel Smith, of Grimsby, all sweet, and possessing no distinctive features to warrant their being disseminated.

Two varieties for a name, shown by A. M. Smith, one a sweet apple, firm flesh, and, apparently, a very good keeper, an improvement on Talman's Sweet. The committee do not know the name, but consider it worthy of cultivation. The other variety is a small, round, red apple, with numerous light dots, name not known to committee.

Some samples of Northern Spy, Golden Russet, King of Tompkins County, and Rhode Island Greening, were shown by Mr. Woolverton, all fine specimens, except the Greenings.

Some medium samples of Baldwin and Newton Pippin, shown by Mr. Ball.

Five seedling apples, shown by Mr. J Cowhead, of Brantford—No. 1 is considered good for cooking, though the sample having been frozen, the committee could not say definitely.

No. 2 did not seem to possess anything to recommend it.

No. 3 was of peculiar flavour, and worthy of trial.

No. 4 is very good, long keeper, tree said to be very hardy and a great cropper. The committee consider it a very promising apple, and well worthy of extensive trial.

No. 5 has a pleasant sub-acid flavour, but not superior to other apples of same season now in cultivation.

Also, three very fine specimens of Northern Spy, shown by the President.

A sample of Prince's St. Germain Pear was shown in a bad state of preservation.

Moved by Mr. Holton, seconded by Mr. A. M. Smith,

"That whereas it is desirable to encourage the propagation and introduction of seedling fruits of merit, suited to the climate of Canada,

"Be it therefore resolved that the sum of FIFTY DOLLARS be given by the Society for the best new seedling late winter apple; THIRTY DOLLARS for the best seedling harvest apple, and TWENTY DOLLARS for the best seedling autumn apple—these to be at least equal to the old popular varieties now in cultivation.

"Successful exhibitors shall place at the disposal of the Society scions of the prize fruit for distribution among its members, to gather with such information as to soil, location, growth of tree, &c., as the committee appointed by this Society to make the award may require."

Also resolved, "That George Leslie, D. W. Beadle, and the mover, be a committee to whom all such fruits shall be submitted, and who shall examine and report to the Society from time to time the results of their examination." Carried."

On motion, adjourned to 7 30 o'clock, p.m.

EVENING SESSION.

This session was first occupied in discussing the methods of gathering, packing, and preserving apples. Mr. O. T. Springer, who has had considerable experience, says that he picks and handles carefully his winter apples, packs them in clean barrels, heads them up, and then places them on their sides, keeping them in an out-shed as long as they can be left without danger from freezing, and then places them in a cellar that is as cool as possible, and at the same time free from frost.

Mr. Latshaw, of Paris—The picking should be very carefully done, when the fruit is dry, always gathering the fruit from the lower limbs first, and progressing upwards until all are gathered, packed into barrels as gathered, sorting the fruit carefully, and allowing no leaves to get into the barrel.

Several other members expressed similar opinions with regard to the best modes of gathering and preserving winter apples.

The Roxbury Russet and Golden Russet, of Western New York, were mentioned as being the best of the long keeping sorts. The Esopus Spitzenberg was considered by all to be one of the very best of the winter apples, being of fine appearance and superior flavour, but not a variety to be planted for profit.

A lengthened conversation was had upon the habits of certain insects injurious to fruit trees and fruit, in which much interesting and useful information was imparted by Mr. Saunders, of London, Entomologist to the Association.

It was moved by Mr. Burnet, seconded by Mr. Saunders,

"That the best thanks of this Association are due, and are hereby tendered, to Thos. Swinyard, Esq., Manager of the G. W. Railway, for his courtesy in granting the members return tickets over the road at quarter fare." (Carried.)

On motion of Mr. Burnet, seconded by Mr. Arnold, Resolved,

"That the Hon. J. Carling be elected a life member of this Association." (Carried.)

On motion of Mr. Arnold, seconded by Mr. Saunders, it was resolved.

"That the thanks of the Association be returned to the County Council of the County of Wentworth for the free use of their Council Chamber, for the purposes of this meeting."

At 10 o'clock p. m. the meeting adjourned

Meeting of the Directors of the Fruit-Growers' Association of Ontario.

Present—W. H. Mills, Esq., President J. C. Rykert, Esq., Vice-President; Rev. R. Burnet, Chas. Arnold, J. R. Martin, W. Saunders, Lewis Springer, A. M. Smith, and the Secretary.

Minutes of last meeting read and approved.

Communication from Mr. J. Freed, respecting the offering of premiums for Strawberries was read.

Resolved, that it is inexpedient to adopt the suggestions contained in Mr. Freed's communication at present.

Resolved, that the President and Vice-President be requested to lay before the Commissioner of Agriculture the importance of obtaining an Annual Report on the subject of insects injurious to fruits and grains by a competent entomologist.

Resolved, that a prize of THIRTY DOLLARS be offered for the best essay on the cultivation of the Raspberry, Blackberry, Strawberry, and Currant, and a further prize of FIFTEEN DOLLARS for the second best essay. Each essay not to exceed eight printed pages, octavo, and to be forwarded to the Secretary. D. W. Beadle, Esq., at St. Catharines, on or before the first day of September next. Each essay to bear a motto, and to be accompanied with a sealed note having the motto endorsed upon the outside, and containing within the name of the author of the essay.

Resolved, that Messrs. W. L. Copeland and W. J. McCalla, of St. Catharines, be appointed Auditors of the Treasurer's accounts, with the request that when they have completed their audit they report in writing to the President.

Resolved, that the summer meeting of the Association be held in Galt, at a time to be fixed by the President, and that the subjects for discussion be the small fruits.

The Western New York Fruit Growers Society.

This society held its winter session in the city of Rochester on the 27th and 28th of January.

After the election of officers for the ensuing year, the following questions were adopted for discussion, namely:

1. What variety of quince is worthy of cultivation?

2. Can the cultivation of the gooseberry be made profitable?

3. What varieties of the gooseberry are worthy of cultivation?

4. What species of deciduous trees are most desirable to plant for shade and ornament, or timber?

5. What species of evergreen trees are most desirable for planting for ornament or protection?

6. Can the cultivation of the plum be made profitable?

7. What varieties of plums are most profitable for market?

8. What varieties of plums are best for the amateur?

9. Should the originators of new varieties of fruit be protected by law, in the same manner as inventors?

10. Is it more profitable to raise prolific fruits or high flavoured fruits?

11. What is the best material and form of trellis for training grape vines?

12. Is there any efficient and inexpensive mode of exterminating the canker worm?

It seemed to be the prevailing opinion that the best variety of quince was the well-known apple-shaped or orange quince, although no vote was taken.

With regard to the cultivation of the gooseberry, so much difficulty had been experienced from mildew, and of late years from the gooseberry saw-fly, which stripped off the foliage and destroyed the plants, that evidently not much attention had been given to the cultivation of this fruit, and nothing definite was arrived at upon the second and third questions.

The fourth question excited considerable discussion. The suggestion was made by Mr. Hooker that our forests should be regarded not as a thing to be preserved but to be renewed, and the timber regarded as a crop to be taken off when at its proper stage of growth; in short, that timber should hold its place in the greater cycles of rotation of crops.

The native elm was thought to be one of our most graceful and desirable ornamental trees; also the sugar maple, especially when planted in clumps; and the silver-leaf maple for planting singly. The Norway maple was highly esteemed as a beautiful species that grew rapidly. The tulip tree was very much admired, but it was difficult to transplant it. The different varieties of the linden or bass-wood were held in much esteem, particularly by bee fanciers. The horse-chestnut was mentioned as being suitable for lawns. The European larch was very highly spoken of as a rapid-growing and beautiful tree, and at the same time very valuable for timber. The locust was also very valuable, but of late years had been almost destroyed by the locust borer. One gentleman remarked that land worth fifty dollars per acre was too valuable to be planted with timber. One crop of wheat had returned him more money to the acre than the wood which he had cut from the same land, that had been a century in growing. Another suggested a material difference in the value of wood as fuel, and that which was truly termed timber, and suited to more valuable purposes.

In response to the 5th question, it appeared that the Norway spruce was the general favourite. Some favoured planting wide belts, and others only a single row, as a protection from the prevailing high winds. All agreed as to the beneficial effects of such a screen or wind-break, and the subject of planting for ornament was lost sight of in the more pressing thought of planting for shelter.

The 6th, 7th, and 8th questions were considered together, and no very definite conclusion reached. The old enemy of the plum, the curculio, came in for his share of consideration, and various methods of killing or driving him away were suggested. One gentleman thought he had succeeded in so offending his nostrils by placing corn-cobs soaked in coal-tar in the trees, that he left in disgust. The black knot also received attention, and the old question whether this was caused by the curculio was revived. That it is not caused by the curculio is now the more generally received opinion.

The 9th question elicited quite an animated debate. The proposition that he who expends time, thought, labour, skill and means in the production of a valuable new fruit, ought to be protected by a patent as justly as he who produces a new machine, was well and forcibly put. But the majority of the members, while admitting that the originator of a new and valuable fruit deserved to be rewarded, maintained that it could not be done by patent. Some maintained that the honour of being the originator of a popular new fruit was sufficient remuneration, and others favoured the granting of Government bounties to the originators. No definite action was taken on the question.

The tenth question was considered at some length, and the general tone of the meeting evidently favoured the growing of the more choice varieties of fruit. It was suggested that if these varieties were grown by all fruit cultivators, the quantity thrown on the market would be so great that the price that could be obtained for the highest flavoured fruits would be no greater than for the more prolific sorts. To this it was replied by Mr. Hogg, of Lockport, that the demand for the best fruits had fully kept pace and would keep pace with the supply, and he stated that the Delaware grape now sold for twice as much as it did ten years ago. Mr. Crane had kept an accurate account with two rows of Concord grape vines and two rows of Delawares, and found that the Delawares returned him twice as much as the Concords. Another suggested that very much depended upon the manner in which fruit was put up and sent to market, and that often by careful selection a high price can be obtained for one half or less of the fruit in a barrel, when the whole would hardly sell at any price.

The eleventh question was left undecided. A couple of gentlemen occupied the time in describing how they made trellises for grape vines. One of them had just patented a new spiral trellis

The discussion of the twelfth question made very apparent the fact that many intelligent fruit growers knew very little about entomology. The same insect was spoken of under names indicating several distinct species, and diverse species were spoken of as one and the same insect. The meeting very wisely appointed a committee of five, charged to obtain all the information possible in relation to the canker worm and all other varieties of worms that prey upon fruit and shade trees, and the best means of prevention or destruction, and report at the next meeting of the Society.

There was a fine collection of winter pears exhibited by Messrs. Ellwanger & Barry, of Rochester, embracing twenty-five varieties. There were also some horticultural implements, and boxes and baskets for packing grapes and berries for market, on exhibition, which attracted considerable attention.

Toronto Horticultural Society.

The Toronto Horticultural and Botanical Gardens Society held its annual meeting on Tuesday, Feb. 16, in the Mechanics' Institute, Toronto—the President, Hon. G. W. Allan, in the chair.

The Rev. E. Baldwin read the report, which showed that the sum of $157 90 had been added to the balance of $217 12, with which the past year was commenced, so that the Society begin this year with a balance on hand of $374 02, the gross receipts being $2,765 01, while the expenditure was $2,390 02.

After the adoption of the report, the following officers were elected:—

President—Hon. George W. Allan; 1st Vice-President, Mr. James Fleming; 2nd Vice-President, Mr. P. Armstrong: Corresponding Secretary. Mr. W. S. Lee; Recording Secretary, Mr. J. A. Simmers.

DIRECTORS—Rev. E. Baldwin, Messrs. T. D. Harris, George Leslie, sen., Professor Buckland, J. A. Simmers, George Vair, S. Platt, W. Ince, J. Paterson, J. Grey, F. W. Coate, J. Gibson, Isaac Gilmour, J. Forsyth and Alex. McNabb.

AUDITORS—Messrs. F. Small and G. W. Buckland were appointed Auditors for the ensuing year.

Unleached Ashes for Orchards.

A subscriber, writing from Hamilton, enquires whether ashes would be injurious to orchards if applied unleached. In reply, we would say, there is no objection whatever to the use of unleached ashes, only they must not be applied in as large a quantity at a time as leached ashes. Our correspondent's orchard being in sod, he might spread on the unleached ashes at the rate of sixty bushels to the acre, early in the spring, and carefully plough the sod under, cutting a thin slice not more than four inches deep, and allow it to decay. This will form an excellent top-dressing for his orchard.

Potato bugs have become very numerous and destructive in Ohio. Mr. A. C. Larcomb, of Portage, in that State, from less than an acre of potatoes, killed *four bushels of potato bugs* by actual measurement.

We know a cultivator who had heavy crops of plums for seventeen years in succession, his swine for these seventeen years, without a season's interruption, being allowed the run of the yard.—*Country Gentleman.*

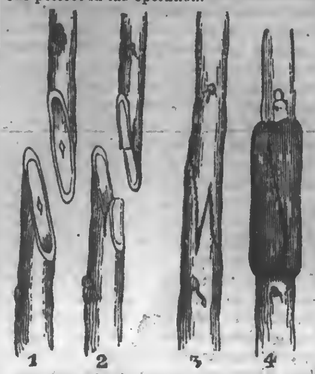
Grafting.

Enquiries on the method of grafting have been so frequently repeated lately, that although an article and illustrations on the subject were given in the last volume of the Canada Farmer, there is no doubt that the following directions, which, together with the accompanying figures, are taken from the *Rural World*, will be acceptable to many of our readers.

In the early settlement of the country, fruit trees were generally propagated from seed. But trees propagated in this way, from kinds however good, gave no assurance that the seedling trees would produce fruit with the good qualities possessed by the parent. New varieties are thus produced, but generally, where one seedling tree produced fruit equal or superior to its parent, many would prove inferior, and frequently they are so degenerated that they are worthless. In order to obviate this difficulty, and to propagate those kinds only that are worthy of cultivation, grafting and budding are resorted to. Grafting was understood by the ancients. Fifty or more different methods were practised by the Romans. But since the demand for fruit trees in this country calls for them by thousands, but two different modes of grafting are generally practised, and these are such as can be performed with the greatest facility.

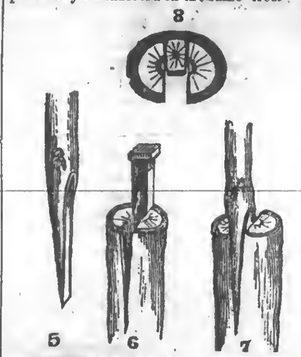
The most common method of grafting apple trees now practised by extensive nurserymen is to sow the apple seed either in the fall or spring. The seedling, on good land and properly cultivated, will, by fall, be large enough to graft. These are taken up and packed in the cellar, and the business of grafting is carried on through the winter. The grafts are packed in boxes, mixed and covered with moss, pulverized rotten wood or light earth, and placed in the cellar until the season of setting out arrives in the spring. Roots, grafted in this way, are cut into two or more pieces, according to their size and length, each piece forming a root for an individual tree.

If the graft is set in the stock or root, so that the sap may flow upwards without interruption, and that which is elaborated by the swelling bud and leaves may flow freely downward through the inner bark, the union is surely and readily formed. In order to secure this, certain requisites are to be regarded, the first of which is, that the operation be performed with a sharp knife, so that the parts may be cut smoothly, without mutilating the pores or sap vessels, and the two parts be brought into immediate and even contact. Secondly, that the parts be so brought together that a permanent and considerable pressure be applied to keep the parts in their proper places. Thirdly, that the union of the inner bark and the wood, both of the graft and the root, be brought together, so as to exactly correspond. Where the graft and the stock are not of the same size this union must be secured on one side. With a correct knowledge of the requisites for grafting, a little practice will soon make one perfect in the operation.



Formerly, the stocks at one year old were set in the nursery rows and cultivated one year, and then grafted at the surface of the ground. It is contended by some that trees propagated in this way are better and longer lived than those that are root grafted. Our experience does not enable us to answer this question. The last is a more tedious and expensive operation, and can only be done in the spring, when other operations are pressing. In some nurseries stocks are set in the way we have mentioned, and budded in the fall at a comparatively more leisure time.

Another method of grafting is extensively practised in seedling orchards, by removing the large limbs and inserting grafts in their stumps, or where it is desirable to have specimen fruit. A great variety of apples or pears may be inserted in the same tree.



The figures we give above will illustrate the various methods now generally practised in grafting fruit trees. Figs. 1 to 4 represent the successive stages of what is termed whip or tongue grafting, from the sloping cut of the graft and stock or root to the completion of the operation by binding. In practising this method of grafting, with one clean cut we make the proper slope, and, by reversing the knife, one cut downwards completes the tongue. In making the tongue, the cut downwards should be deeper than is represented in figures 2 and 3; it should be at least three-quarters to one inch deep. This increased depth adds greatly to the strength of the parts united. Figures 5, 6, 7 and 8 represent the respective parts of what is termed cleft-grafting, such as is usually employed in stocks planted in the ground, and in renewing the heads of old trees. Figure 6 represents the stock, opened with a wedge, ready to receive the graft. Figure 5 represents the wedge shape of the graft to be inserted, and figure 7 illustrates the graft in its place after the wedge has been withdrawn. It is only large stocks that require to be opened by a wedge. Nursery stocks are always grafted while they are so small that the graft itself will open the cleft. Figure 8 shows a cross section of the cleft graft. It will be seen that the graft is cut thicker on the outside than on the inside, in order that the points of union at the bark may fit the more firmly.

In figure 4 the band is represented. Our method of binding is somewhat different, and may be performed with great expedition.

Take a piece of board with a planed surface, a yard long and nine or ten inches wide; draw a line with a pencil the entire length four inches from one edge, and draw another four inches from the first. These indicate the length of the bands. Along the edge of the board and along each line lay on with a brush a strip of grafting wax one inch wide. For making the bands provide common cotton cambric, worth 25 cents per yard. Draw the end of the cloth even with the second line made on the board, and stretch the cloth and press it on to the wax, so that it will adhere, and cut off the piece with a knife, even with the edge of the board. Then apply a coat of grafting wax one inch wide along the two edges of the cloth, and one inch wide on each side of the middle line. Then, with a sharp knife, across the board, cut the cloth into strips half an inch wide, and then draw the knife lengthwise over the middle pencil mark, cutting the bands into two lengths of four inches each. By a gentle fire the wax is kept at a proper temper, and the bands may be taken from the board as the binding proceeds, and applied to the grafts with the greatest facility.

When the stocks were of good size and the grafting well performed, we never found any great benefit from binding.

Grafting wax may be made by melting together about equal parts of beeswax, tallow and rosin; or the proportion of wax may be reduced for the sake of economy, and the rosin and tallow supplied in proportions that will give the proper temper to work readily and adhere well.

Camellia Count Esterhazy.

We present our readers with an engraving of a beautiful Camellia, from a plant in the collection of the Hon. D. L. Macpherson, Chestnut Park. Mr. Vair gives the following brief description of this new variety:—The habit of the plant is vigorous, leaves medium-sized; the colour of the bloom is a reddish crimson, deeper towards the margin: petals slightly veined or reticulated. But the great attraction is in the peculiar screw-like formation of the bloom itself, as will be seen by referring to the engraving.

Annual Report of the Fruit Growers' Association.

We would call attention to this very valuable report, which will be found as Appendix G. to the report of the Commissioner of Agriculture. It occupies something over fifty pages, and contains the constitution and by-laws of the Association, the President's address at the annual meeting, the prize essay on the cultivation of the apple, an article on hybridizing and crossing the grape, and another on the apple worm; a report on the Philadelphia raspberry, report on Mr. Bishop's Canadian seedling strawberry, besides reports on the different varieties of fruit from twenty different parts of the Province. It should be in the hands of every cultivator of fruit in Ontario. Every member of the Association is entitled to a copy of the report, and it alone is well worth the small annual member's fee of one dollar. Any person can become a member by sending to the Secretary, at St. Catharines, an intimation of his desire to do so, and enclosing the sum of one dollar. Every one interested in raising fruit will find himself well repaid by the information obtained in regard to the growing of the different kinds of fruit, and the best sorts to grow. Several meetings are held during the year in different places, and any place represented by twenty-five members is entitled to have a meeting held there, if desired. Hitherto the meetings have been held only in Hamilton, Toronto and St. Catharines, but as members increase in different sections of the country, the meetings will be held in other places. We expect that this Association will soon number among its members all the lovers of fruit in Ontario, and that it will prove of incalculable benefit in developing the fruit-growing capabilities of our Province.

The Nova Scotia Fruit Growers' Inter-Provincial Prize.

To the Editor.

Sir,—At the annual meeting of the Nova Scotia Fruit Growers' Association and International Show Society, held yesterday, I was instructed to forward to you for publication the accompanying report of the gentlemen who were judges on collections of apples competing for the Inter-Provincial prize at the late Exhibition in Halifax.

As a letter has recently appeared in The Globe on this subject, and one very desirable object in the Confederation of the Provinces of the Dominion is that we should become better acquainted with each other, and with the resources and capabilities of the respective Provinces, I may be permitted to add a remark or two with reference to this Exhibition and competition, more especially

as it is hard for many, who have not personal acquaintance with Nova Scotia, to believe that we have made such progress in fruit cultivation as will enable us to compete with other parts of the Dominion, or that our climate and soil will admit of it.

Allow me to say, then, that under an arrangement with Mr. Kilborn, the exhibitor of the Ontario collection, I took charge of the fruit on its arrival, unpacked it myself in the Exhibition Building, and had it carefully arranged and well placed, in the same court with the Nova Scotia collection, and that the apples were in perfect order.

The judges appointed were Charles E. Brown, Esq., of Yarmouth, a gentleman who occupies the foremost place in that county as an experienced and successful cultivator of the finer sorts of fruit; Robert W. Starr, Esq., of Cornwallis, who is second to no one in this Province as a critical judge of apples, and who for several years past has devoted a good deal of attention to their nomenclature and classification; and Alfred Saunders, Esq., late Secretary of the Royal Horticultural Society of the Island of Jersey, and now residing in Halifax. Only one of these gentlemen is a member of the Fruit Growers' Association, or in any way connected with it.

I think it will be admitted that from such a jury an intelligent and impartial award was to be expected; and while regretting any disappointment that may be felt in any quarter as to the result of the Exhibition, I am quite confident that no person who saw and examined the collection in Halifax will say that there could be any question as to the justness and propriety of their decision.

We can, and do, raise superior fruit in Nova Scotia, and in considerable quantities. It may be, however, that with longer notice, and more careful and extensive preparation, a collection of apples can be got together in Ontario which will entirely outshine anything we can produce. The fruit-growers of Nova Scotia will be happy to meet their brethren of Ontario at any future occasion in friendly and honourable competition; and whatever party bears away the palm next time, at least the great advantage will result that we shall be becoming better acquainted with each other, and doubtless be better friends in consequence.

JOSEPH R. HEA,
Sec. F. G. Association.

Wolfville, N. S., Jan. 20, 1869.

JUDGES' REPORT.

To the President of the Nova Scotia Fruit Growers' Association and International Show Society.

SIR,—We, the undersigned, appointed by the Council of your Association to examine and report upon the collections of apples in competition for the prize of one hundred dollars and a gold medal, offered for the "best collection of apples from any Province of the Dominion," having carefully examined the same as regards number, size, perfection and quality, beg leave to report as follows:

We find but two collections entered—one from Ontario and one from Nova Scotia. The one from Ontario numbers about sixty sorts. That of Nova Scotia contains over two hundred varieties.

In the comparison of standard varieties common to both collections, we find that those grown in Nova Scotia are much the largest and finest in the majority of cases, while in *some* instances the flavour of those from Ontario was superior to the others.

Of the described and recognized varieties there is a much larger proportion in the Nova Scotia collection than in that from Ontario. The number of standard or recognized varieties described by the American pomologists, Downing, Warder, Thomas, &c., contained in the Ontario collection, was about twenty sorts, while Nova Scotia had nearly ninety. Of those marked in their respective lists as native varieties and seedlings, Ontario showed eighteen, few of which were worthy of notice; and Nova Scotia about forty, many of which were superior both in appearance and flavour. The remainder of the Ontario collection was made up of medium and small-sized kinds, some of them very inferior in flavour and appearance, with apparently local names; but, in some instances, the names of superior fruit wrongly attached.

In the Nova Scotia collection, twenty-eight sorts were labeled with the growers' names only, being (as was explained to us) the produce of young trees imported from New York, and the names lost; some of these were very fine in appearance and flavour; the remainder appeared to possess local names, some of them being well known in the country.

In the comparison of the same sorts in the two collections, we find Northern Spy and Snow-apple equal in size and colouring, while the Ontario Snow-apple has the highest flavour. King of Tompkins County, Rhode Island Greening, Blue Pearmain, Talman's Sweet (misnamed Danvers Sweet, see Warder p. 557), Twenty Ounce Pippin (misnamed Baldwin, see Warder, p. 461), and Gloria Mundi (misnamed white Spanish Reinette, see Downing, p. 214), of the Ontario collection, were much smaller, and in other respects not better than those grown in Nova Scotia. Ribston Pippin, and Yellow Bellefleur, of the Ontario collection, were quite small and inferior in appearance, while those of Nova Scotia were very large and well grown. The Gravenstein from Ontario, although much the smaller, was beautifully coloured and exceedingly high flavoured.

Of other varieties worthy of notice in the Ontario collection, we find Twenty Ounce Pippin (which seems to be the Twenty Ounce or Cayuga Redstreak of Downing and Warder), and Ramsdell's Sweeting, very large, good flavoured and handsome; Fall Pippin, and Black Detroit, large and fine; Yellow Newtown Pippin, Seek no Further, Butter Apple, Vandervere, Spitzenberg, Branslaugh's Seedling No. 4, and Fleming's Seedling No. 3, were of good medium size and flavour. Out of the numerous small sorts we only select two as worthy of particular notice, namely, James' Dessert, and Corwin's Winter Russet, both rich, and of high flavour.

In the Nova Scotian collection we find, of noticeable varieties, in addition to those already mentioned, the Emperor Alexander, Blenheim Pippin, Pound Sweet, Mammoth Russet, Broadwell, Early Bough, Keswick Codling, Dutch Codling, Sweet Russet, Drap d'Or, Golden Globe, Golden Ball, Canada Reinette, Colvert, Swaar, Hutchings' Seedling, Pumpkin Sweet, Golden Sweet, Cat Head, Ox Apple, and Micmac, which are large to very large, and many of them fine flavoured.

From the medium sized we select Autumn Strawberry, Porter, Williams' Red, Saxon, St. Lawrence, Munson Sweet, King of the Pippins, Calville Rouge, Early River, Autumn River, Rambo, Court-pendu-plat, Hubbardston's Nonsuch, Malden's Blush, Æsopus Spitzenberg, Flushing Spitzenberg, Minister, Lyscom, Baldwin, Herefordshire Pearmain, Concord Pearmain, Delaware, Harvey, Striped Gilliflower, Summer, Bellefleur, Nonpariel, Roxbury Russet, Golden Russet, Hunt's Russet and Norfolk Beaufin, as well known standard varieties. From those marked native sorts, we select Calkins Pippin, Early Calkins, Sweet Calkins, Bishopsbourne, Sweet Redstreak, Morton's Red, Fall Pippin, Sandford's Blush, Port Wine, Johnson's Red, Jackson's Fancy, Pierce Apple, Pudsy Apple, Bellevue, Stair's Seedling, Black's Red, Segee, Willoughby, Margaret Pippin and Christmas Sweeting, for size, appearance and flavour.

Among the unknown varieties we particularly notice the kinds labelled Greenough, Lawson, W. Eaton, Ross, North, Harris, Woodworth, C. Sandford, Barss, Manning, Wilson and Dickie, as being large, handsome apples. We also notice a few of those small varieties which, although not profitable to the producer, rank high with the connoisseur as dessert fruit, namely, Pomme Grise, Golden Pippin, Royal Pearmain, Golden Reinette, Court of Wick, and Pomme d'Api.

In conclusion we would remark that, on the whole, the collection from Ontario cannot be considered a superior lot of apples, coming as they do from what we have always been led to believe was one of the best fruit-growing districts of the Dominion.

We, therefore, in view of the results of our comparisons—first, by number of kinds; second, by standard varieties; third, by identical sorts in the two collections; fourth, by size, appearance, and marketable value of the remaining kinds—have not the slightest hesitation in awarding the prize given by your Association, to the collection from Nova Scotia.

Given under our hands at the Exhibition Buildings in Halifax, this eighth day of October, A.D. 1868.

(Signed)
C. E. BROWN.

Book Notices.

THE TRANSACTIONS OF THE MASSACHUSETTS HORTICULTURAL SOCIETY, [BOSTON] for 1868, forms a very neat pamphlet of over one hundred pages, containing some very interesting information.

From the report of the committee on fruits, by W. C. Strong, Esq., our esteemed friend of earlier years, we learn that Hovey's seedling strawberry yet maintains its position among market men, but that the Wilson is steadily gaining upon Boston prejudice. The Jucunda gained friends last year. Agriculturist was unproductive. The new seedling raised by Hon. Marshall P. Wilder (considered worthy of being named "President Wilder") is reported "of largest size, superior in quality, beautiful in appearance, and firm enough for market purposes."

Cherries were scarce. Among currants the La Versaillaise is first on the list, yet this fruit is reported as becoming scarce in Boston market and enhanced in price. In raspberries, the Knevitte Giant "is the leading and prize kind." This fruit is also scarce and very high. The culture of the older sorts of blackberry is decreasing, and the newer varieties not yet exhibited. The Mountain seedling gooseberry was first among American kinds. In pears the Doyenne d'Ete appeared 1st of August. Beurre Giffard took the first prize on the 15th of August. Rostiezer was best August 29th and September 5th. At the monthly exhibition on the 10th October the best dish was Sheldon; second, the Urbaniste; third, the Beurre Bosc. On the 14th November, the award for winter pears placed Caen de France first, Lawrence second, and Beurre d'Aremburg third.

There was an excellent crop of apples. The Williams received the first prize for summer, Gavenstein for fall, and Northern Spy for winter. In grapes, notwithstanding an extremely unpropitious season, there was a fair exhibition. The lowest wholesale price for Concords, of fair quality, was $12 per hundred pounds. The Framingham was reported identical with the Hartford, or so nearly so as to be undeserving a separate name. The "Main" is again pronounced to be only the Concord, and not a new grape at all. Israella and Adirondac took the prize as the best early grapes, September 11th. Arnold's new hybrid grapes were exhibited by Rev. W. H. Wilcox.

A special prize of sixty dollars was given to the pear "Clapp's Favourite," after a trial of five years, as the best seedling pear.

The report of the committee on plants and flowers is by Mr. J. C. Hovey, but there is very little in it of interest to the general reader. If in addition to stating that the first prize for the best collection of forty varieties of hardy perpetual roses was awarded to J. C. Chaffin, the worthy chairman of the committee had mentioned the names of those varieties, we should have been able to have informed our readers which roses were held in most esteem among Boston rose fanciers. The Gloire de Nancy geranium is mentioned as being one of the best double flowered varieties yet introduced.

From the report of the committee on vegetables, by C. N. Brackett, we learn that the General Grant tomato is early, productive, solid, and of fine flavour, and received the first prize over all others for two successive years, and that so far as can be affirmed from a single year's experience, the Early Rose Potato is the most promising early potato of the finest quality, and wonderfully productive.

The report of the committee on gardens is exceedingly interesting, and from reading it we infer that this Horticultural Society has a standing committee whose duty it is to visit such gardens as are brought to their notice, under certain regulations, and to recommend the award to the proprietor of any of these gardens of such sum as they may think to be merited by reason of any feature in the cultivation, or of any particular skill displayed or success attained. For example, the committee award to Col. Wilder twenty dollars for his successful experiments in hybridizing *Lilium lancifolium* with *L. tigrinum*, and, what was more astonishing, the impregnation of the Japan lily by the *Gloriosa superba*. We commend this feature to the consideration of the members of our own Horticultural Societies.

TILTON'S JOURNAL OF HORTICULTURE.—The numbers for January and February were laid on our table together, though copies were sent us promptly at date of issue. Owing to the failure of the copies first mailed to come to hand, we have not been able to notice this handsome magazine earlier. The January number contained a coloured lithograph of the "President Wilder" strawberry, which has been highly commended by the Fruit Committee of the Massachusetts Horticultural Society. The publishers have purchased the entire stock, and a plant of it will be presented to every subscriber to the magazine for 1869. Both numbers are finely illustrated with engravings of flowers and fruit, and filled with very interesting and valuable articles by such eminent horticulturists as Marshall P. Wilder, John Ellis, Joseph Brook, &c., &c.

THE "GARDENER'S MONTHLY," for February, contains a large amount of interesting horticultural matter. It gives a timely caution to its readers on the subject of Orange quince trees, one that may be of value to some of the readers of the CANADA FARMER. The planting of the quince has been largely on the increase, and the demand for Orange quince trees had exceeded the supply; and there are men who will send out the Angers quince to fill orders for Orange, because the Angers quince of that size costs them no more than $60 per thousand, and the Orange quince can scarcely be had at $250 per thousand. An article by the editor on the "Feeding Roots of Trees," goes far to sustain the views of our esteemed correspondent "C." It says that the root fibres of trees are only annual; that, like the leaves, they die every year; and that these root fibres will be found to be nearly all on the surface, decreasing in number and importance with every inch of depth, so that at a depth of one foot from the top scarcely a fibre will be found, only large roots—tap roots—but no root of the slightest benefit to the nutrition of the tree.

THE GRAPE CULTURIST, a monthly journal devoted to grape culture and wine making, edited by George Husmann and Charles H. Frings, is published at St. Louis, Missouri, at $2 per annum in advance. The January and February numbers have just been laid on our table, and are full of practical articles of great interest to those who are interested in the culture of grapes and the making of wine. The publication of such a journal is an indication of the great interest taken in the culture of the vine in the United States, and will be of great value in affording a medium of interchange of experience, as well as by imparting to beginners the stores of knowledge which its able editors have amassed in the course of many years' devotion to the science.

THE GRAPE-GROWERS' GUIDE, a plain and practical work upon the management of the grape vine. By J. Kuch, Waterloo, N.Y., price 25c. The system adopted by Mr. Kuch is the same as that recommended by Mr. Fuller in his treatise on the grape.

Catalogues Received.

Frost & Co.'s Descriptive Catalogue of Select Green House, Hot House and Bedding Plants, Bulbs, Dahlias, &c., cultivated and for sale at the Genesee Valley Nurseries, Rochester, N.Y.

Frost & Co.'s Descriptive Catalogue of choice Flower Seeds, imported in the spring of 1869. Genesee Valley Nurseries, Rochester, N.Y.

Frost & Co.'s Wholesale Catalogue or Trade List of Fruit and Ornamental Trees, Shrubs, Roses, Bulbs, &c., for the spring of 1869. Rochester, N.Y.

VICK'S ILLUSTRATED CATALOGUE.—By an oversight, we omitted, in noticing this excellent catalogue, to publish Mr. Vick's address, which is Rochester, N.Y., U. S.

Annual catalogue of choice and select Garden, Flower and Field Seeds, cultivated for and sold by John Vanderbilt & Brothers, No. 23, Fulton Street, New York.

Ellwanger & Barry's Wholesale Trade List of Fruit and Ornamental Trees, Shrubs, Roses, Dahlias, Bulbs, &c., &c. Rochester, N.Y.

Annual Trade List of the Cherry Hill Nurseries, West Chester, Penn., spring of 1869. Hooper Bro. & Thomas, proprietors.

Catalogue of Arnold's Canadian Hybrid Grapes and Raspberries, from Charles Arnold, Paris, Ontario. This is a descriptive list of the new seedling grapes and raspberries raised by Mr. Arnold, and now for the first time offered to the public.

P. M. Watson's Catalogue of Select Fruit and Ornamental Trees and Shrubs, Roses, Bedding Plants, Greenhouse Plants, &c., &c. Old Colony Nurseries, Plymouth, Mass.

This catalogue also embraces a list of garden seeds, fruit and ornamental tree seeds and flower seeds.

Ellwanger & Barry's Descriptive Catalogue of Fruits, illustrated with engravings of dwarf fruit trees and of small fruits. It is a very full and useful list of the fruits now in cultivation in one of the most extensive and enterprising nursery establishments on the continent, giving, in a few words, the quality and value of the several fruits. Rochester, N.Y.

SIMMERS' CULTIVATORS' GUIDE FOR 1869.—A descriptive catalogue of Agricultural and Garden Seeds, by J. A. Simmers, Toronto, containing brief and clear directions for the cultivation of vegetables and flowers, and much useful information on a variety of horticultural subjects. The catalogue is profusely illustrated. Mr. Simmers advertises for sale, among other novelties, the Early Rose Potato.

Hovey & Company's Illustrated Catalogue and Amateur Cultivator's Guide to the Flower and Vegetable Garden, &c., &c., 53, North Market Street, Boston, Mass.

This catalogue occupies nearly one hundred and fifty pages, closely printed, containing directions for the cultivation of annual, biennial, and perennial flower-seeds, with special directions to amateur cultivators, and plans for flower-beds, descriptions of flower and vegetable seeds, of gladiolus, Japan lilies, and other bulbous flowering plants, and is profusely illustrated with engravings of the most interesting plants, flowers, and vegetables, and ornamented with two coloured lithographs. Price 25 cents.

WASHBURN'S AMATEUR CULTIVATOR'S GUIDE TO THE KITCHEN AND FLOWER GARDEN.—We thought, on receiving Vick's Catalogue, there was nothing to equal it, but we were mistaken. The above Guide and Seed Catalogue is a handsomely got up volume of 152 pages, illustrated with cuts, and also eighteen lithographs of some of the new varieties of potatoes, tomatoes, and flowers, some of these coloured after nature. It is published by Washburn & Co., of Horticultural Hall, Boston, Mass., the oldest established seedsmen in America, and sent on receipt of 50c. We notice that they keep for sale seed of all the favourite English grasses and forage plants.

John A. Bruce & Co.'s Descriptive Catalogue of Agricultural, Garden, and Flower Seeds. Culinary Roots and Flowering Bulbs. 52 King Street West, Hamilton.

This is Mr. Bruce's eighteenth annual edition, and contains, besides the usual list of farm and garden seeds, a special list of all the novelties in that line, including the new potatoes, the report of the judges on the Wentworth turnip match, lists of hardy native and select foreign grapes, strawberries and garden implements.

Mr. Bruce's establishment in Hamilton contains besides an excellent assortment of the above articles, standard works on Agriculture, Horticulture, and Rural Economy.

Ferre, Batchelder & Co.'s Catalogue of Seeds, Vegetable and Flower Garden Manual, comprising a list of all the valuable varieties of American growth, together with many rare varieties, novelties, &c., with special directions for their cultivation, to which is added a list of summer flowering bulbs and small fruits, containing 80 closely printed pages. Price 10c. 231 Main street, Springfield, Mass.

Longevity of Fruit Trees in Britain

During my visit to England last summer, I was not a little surprised at finding, in the lower part of Kent, a gooseberry bush in full bearing, which originated from a cutting I sent from Lancashire forty-two years ago! There can be no mistake as to its identity, it having been in the possession of the same person for the greater part of that period. Several other bushes of different kinds, raised from cuttings sent from the same place and at the same time, were alive and bearing but a few years since. The soil is a good clay loam, and the situation freely exposed to light and air. The bushes were annually thinned by judicious pruning, and otherwise well cared for. Insect depredations were vigilantly kept down, and mildew all but entirely unknown. The variety in question is the "Roaring Lion," a sort very popular many years ago; the berries last summer were, notwithstanding the drought, of good size and flavour, amounting, I should suppose, to considerably more than a quart. The tree, for several years, has gradually evinced symptoms of decline, but for aught that appears at present to the contrary, may survive, with the exercise of the same care, some time yet. It should be borne in mind that the climate of this part of England is much less suited to the gooseberry than that of Lancashire, the south being both drier and warmer than the north-west.

I well remember the gooseberry shows of Lancashire and Cheshire thirty or forty years ago. The size of the berries exhibited was something enormous. I am afraid to state the weight and measurement, lest my memory should mislead. The fruit raised for these competitions was chiefly grown by hand-loom weavers living in the country—a class of men now almost extinct, after a severe and prolonged struggle with steam-power. Horticulture, in several of its branches, owes not a little to this class of work-people, some of whom made considerable progress in the study and advancement of various branches of natural science—botany and entomology in particular. A weaver working in his house could throw down the shuttle at any moment, and attend to the productions of his garden immediately surrounding. He would take as much care—in some instances, perhaps, more care—of his gooseberry bushes, as of his children, reduce the number of berries to a very few, and surround the stems at the surface with muck or moss, and in dry weather moisten it frequently with water, or manure in a solvent condition. On a show day he would often walk many miles with a dozen or two of berries carefully packed in a basket. A copper teakettle was a prize commonly offered in gooseberry competition, and I have seen the celliog of a country weaver's kitchen literally covered with this article, the results of many years' competition, and the owner would point to these trophies with strong feelings of justifiable pride.

The durability of fruit trees, and perhaps of forest trees, in England, is generally much greater than on this side the Atlantic. I observed peaches, nectarines and apricots, trained to open walls, still bearing, that had been planted 30 or 40 years; and also filbert trees of a similar age, still bearing. I gathered some pears of good size and quality of the Poplar variety from the only surviving branch of a tree which was, to my own knowledge, in a decaying condition half-a-century ago! It would appear to be a law of organic life that slow growth and durability are connected as cause and effect.

It is worthy of remark, in travelling through Britain, a distance of only a few hundred miles, say from Cornwall to Sutherlandshire, how exposure and elevation of the surface, rather than mere latitude, affect both animals and plants. Cattle have quite different coats on the eastern to what they have on the western side of the country, arising in great measure from differences in atmospheric humidity. In Cornwall I partook of ripe strawberries grown in the open air in May, and journeying northwards found that delicious fruit coming progressively into season, and finished with some of a most agreeable acid flavour in the north of Scotland, as late as September.

Notwithstanding the abuse which the English climate frequently comes in for, I am of opinion that in no other country in the world has the horticultural art been carried to so high a state of excellence, or it might be said, perfection. From the humble cottage, with its neat little garden of vegetables, fruits and flowers—honeysuckles and roses entwining around its doors and win

dows—to the extensive and picturesque grounds of the lordly mansion, with the necessary adjuncts of orchards and capacious conservatories—the love and progress of this useful and refining art can be distinctly traced. The explanation must be sought for in the harmonious balancing of capital, science, and practical skill, under the general guidance of a correct and elevated taste.

GEO. BUCKLAND.

Bureau of Agriculture,
Toronto, Feb. 7, 1869.

The Apple in Quebec.

To the Editor.

SIR,—I was glad to see in the CANADA FARMER of January, an article on the culture of apples, which I so much want to see attended to down here. I am only theorising, but do think that this Canada East which has so hard a name—these few acres of snow—might be rendered vastly more prolific in the comforts of life. One of the chief of these is in my opinion the *apple*. It is supposed to have been the forbidden fruit, and I am sure that to most people in Quebec city it is such, because of the high price of our imported apples, *and they are all imported*. I argue that they could be produced as far east as this city, for the following reasons:—

1st. Our climate is very like that of Montreal, and Montreal is famous for its apples. We are a little later in the loss of our snow, but that I hold to be an advantage, as it is the late spring frosts, coming after early spring vegetation, which damage fruit trees.

2nd. If nature produced a certain sort of trees in one place, in which place, say, apples will succeed, we have a right to expect they would grow in another neighbourhood in which we found the same sort of trees. Now our bush is exactly the same as that about Montreal.

3rd. If one man can grow an apple tree, so can another under similar circumstances. Further, if one will grow, so would 1,000, or a million. I have known five or six farmers with one or two apple trees flourishing in a district condemned (ignorantly but persistently) as unable to produce the fruit. Here and there in the neighbourhood of this cold corner, apples grow and flourish. I heard yesterday of a gentleman at Charlesbourg, (close to Quebec), possessing an orchard, one tree of which produced eight barrels. I know, a gentleman, H. G. Joly, M. P., who within twenty miles of the city has an orchard which yields very fairly. This gentleman produces greengages in the open air, and has a collection of most delicious plums, larger than an egg, which, together with cherries, are produced in good quantities. Now if one man can do this, I can see no reason why many could not do the same. As I said just now, I am only a theoriser in this matter, because I have had no opportunity of being otherwise at present, but I should be neglecting my duty to my country if I did not call attention to its undeveloped resources, and I do think it a shame that there is so little variety of produce where there might certainly be much more. I hope the extending circulation of your valuable paper will bring about some of these results. If he deserves the blessings of his race who causes two blades of grass to grow where one grew before, much more does he deserve it who induces many men to bring such desirable results about. I know no man who deserves so well of his country as the one who diffuses reliable agricultural information and induces improved cultivation of the soil.

PHIALA.

What Pears to Plant.

A subscriber from London makes the following enquiry:—

"I will thank you, through your next number of the CANADA FARMER, to inform me, to the best of your knowledge, of the names of the most approved kinds of standard pears, as I wish to plant some this spring. Good sized fruit, and to ripen either summer or fall (no winter kinds).

"Also, please say if the spring is a good time to top-dress an orchard with long dung, made this winter."

REPLY BY THE EDITOR—Spring is a very good time in which to apply such a top-dressing to the orchard. It is gratifying to see that sufficient value is placed upon the orchard to induce the inquiry, for heretofore orchards were expected to yield fruit without manuring. The well tried and most approved varieties of standard pears, are, for summer and fall:—

Doyenne d'Ete,
Beurre Giffard,
Osband's Summer,
Tyson,
Bartlett—Beurre d'Anjou,
Belle Lucrative,
White Doyenne,
Flemish Beauty,
Seckel—Sheldon.

The four first named are small-sized in fruit, as are all the earliest sorts. The Seckel also is small, but unsurpassed in quality. The other varieties are of good size, best quality, and give a good succession.

What Shall We Plant?

As spring approaches, the inquiry, "What shall we plant?" is uppermost in many minds. To aid those who are distracted by the claims of the thousand and one things that are all "so beautiful and worthy of a place in every collection," according to the nurseryman's list, we propose to select a few of the trees and shrubs that are planted for ornament, that can be readily obtained, and that have been proven to be really ornamental and valuable. It is not intended at this time to discuss soils, situations, styles of planting, or purposes intended to be served; but presuming the planter understands these details, we now briefly enumerate the most suitable and valuable in our climate.

Of large-growing, deciduous trees, we name the European Ash, English, Scotch, and American Elms, Horse Chestnut, European Larch, European and American Linden, Sugar Maple, Silver Maple, Norway Maple, and the Tulip Tree. These trees are well adapted for streets and avenues, and for planting extensive grounds and parks.

The Purple-leaved Beech, Red Flowering Horse Chestnut, Judas Tree or Red Bud, Purple-leaved Maple, Mountain Ash, English Oak, Virgilia or Yellow Wood, Rosemary-leaved Willow and European White Birch, will be found to meet the wants of those whose grounds are of but limited extent.

Those wishing drooping trees will find them in the Cut-leaved Weeping Birch, the Camperdown Weeping Elm, the Weeping Mountain Ash, New American Weeping Willow, and Kilmarnock Weeping Willow.

Our list of evergreen trees is yet quite incomplete. Many of the most beautiful varieties have not yet been planted in Canada a sufficient time to test their ability to endure our climate. But yet there are some beautiful specimens in this class that can be planted with confidence. Of the large growing sorts we can recommend the White Pine, Austrian Pine, Scotch Pine, Balsam Fir, Norway Spruce, White Spruce, and Hemlock. Those that attain to a medium size are the American Arbor Vitæ, Siberian Arbor Vitæ, Red Cedar and common Juniper; and of those of a dwarf habit we have the Trailing Juniper, Savin Juniper, Tom Thumb Arbor Vitæ, and American Yew.

Are there not some gentlemen of taste who will plant some of the many interesting and beautiful evergreen trees and shrubs that give promise of enduring our climate, and report their success or failure?

The following list of shrubs will be found to comprise those which are most desirable and hardy: The Purple-leaved Berberry, White Fringe, Rough-leaved Deutzia, Double Crenate-leaved Deutzia, Tartarian Honeysuckle, Persian Lilac, Purple Fringe, Japan Quince, Double Plum-leaved Spirea, Double Lance-leaved Spirea, Fortune's Spirea, Rose-coloured Weigilia, and, no doubt, the new Prunus trilobata.

Fruit Competition.

(To the Editor).

Sir—Will you allow me to answer, through the columns of your journals the challenge of Mr. Harris, of Nova Scotia. Now, Mr. Editor, this challenge is given in such a way as to make it impossible for us to accept. In the first place, it meets my eye for the first time on the 6th of February; and his proposition is only for the last year's crop of fruit, and the trial to come off in Nova Scotia; and further, he must have just such varieties as he happens to have on hand, and which, perhaps, not another man in the whole Dominion would have at this late season of the year. Again, he does not give us his rules as to judges, &c.; so that before all those items could be arranged the fruit would be spoiled—especially as our apples would have to be subjected to the accidents incidental to such a journey at this time of year, especially the pounding over 1,000 miles of railway. Now, if Mr. H, or any other Nova Scotia friend, would really like to have a fair competition, we will submit a plan, and appeal to all intelligent and fair-minded pomologists if it is not eminently fair to all parties. Meet us half way—say at Montreal—select 20 of your best varieties, 10 of fall fruit and ten of winter fruit, 12 of each variety—10 varieties to be baking apples and 10 dessert fruit—quality to rule; but stipulate that the samples shall not fall below the medium size, as laid down by Downing. Each of the contestants to select such varieties as may be considered the best from his own Province. Judges to be chosen from the United States. The defeated party to pay all necessary expenses of the contest.

Yours respectfully,

J. C. KILBORN.

Beamsville, February 18.

Pear Growing.

"Cultivateur" writes as follows:—

"Not having any experience in pear growing, I write to you for information. What are the best varieties of summer, autumn, and winter pears for the country in the vicinity of Toronto, say two of each. The soil is a heavy clay? The reason why so few pears have been grown is that we have so few hardy and prodnctive kinds."

Will some of our readers, living at Toronto or vicinity, who have had some experience in growing pear trees, have the goodness to give "Cultivateur" the benefit of their experience?

"How can pear trees be raised from the seed? I have sown the seed several times in the fall, on good soil, but the seeds never germinated, Is there any different manner of sowing them? Are not pear trees raised from the seed more hardy and productive than grafted trees?"

There is no better way. Seed sown in the fall ought to grow. Was it sound seed when sowed? for if it is allowed to heat in the pomace it will not germinate. Or did "Cultivateur" cover it too deep? It needs only a very slight covering. No doubt some of the seedling pear trees will be hardy, perhaps more hardy than those in cultivation; but the quality of the fruit will be very uncertain, unless hybridization or cross-fertilization is resorted to. With a little attention to this, and judicious selection of parents, the results will be as certain as those of the stock-breeder, and good quality, quantity and hardihood be secured in the seedlings. The Buffam, Benrre Diel, Flemish Beauty, Louise Bonne de Jersey and Summer Bon Chretien, have the reputation of being our most hardy pears, and particularly the Flemish Beauty and Bon Chretien. With such varieties as these, there should be no difficulty in securing a hardy and valuable race of seedlings.

New Material for Strings.

A correspondent of the *Ohio Farmer* speaks in high terms of the value of the plant known by botanists as the *Yucca filamentosa*, one of the varieties of the Adam's Needle, for supplying strings as tough as leather, useful for every purpose of the farmer and gardener where strings are needed. He says it grows wild on the Southern Ohio and Mississippi, sending up leaves from three to four feet long. Perhaps it may be profitable to gather the leaves and prepare them for use in these northern parts, where the plant is not found.

To Prolong Flowering.—By cutting off the seed vessels of flowering plants, as soon as the petals drop, the plants will be kept in greater vigour, and the season of flowering be considerably prolonged.

Poinsettia Pulcherrima Poisonous.—As a warning to hothouse gardeners, I think it my duty to inform you of an accident which occurred to Mr. Buck, my gardener. On the 8th of this month, as he was pruning a plant of *Poinsettia pulcherrima*, he cut his thumb, but took no notice of it at the time, so slight was the incision. On the Thursday following, however, he felt an unpleasant prickling sensation in the thumb, which soon extended up the arm. On Friday it was succeeded by great numbness in his right arm and leg, and upon consulting a medical man he found that the poisonous juice of the plant produced these painful sensations. His leg was so much benumbed as to render it useless, but upon further applications of the fomentations and other remedies prescribed, the baneful effects have now subsided, leaving only a few spots on the lower part of his thumb, similar to those of the small pox. Oswald Mosley, Bart., Rolleston Hall.—*The Journal of Horticulture.*

Agricultural Intelligence.

Agriculture and Arts Association of Ontario.

FIRST MEETING OF THE BOARD.

The newly-elected Council of the Agriculture and Arts Association of Ontario met for the first time since the re-organization of the Board under the provisions of the present Act, at the office of the Association, on Wednesday, February, 24th. The following elected members of the Board were present:—The Hon. David Christie, Paris; Hon. J. Skead, Ottawa; Andrew Wilson, Maitland; John Walton, Peterboro'; Geo. Graham, Brampton; James Cowan, Waterloo; J. C. Rykert, M. P. P., St. Catharines; Robert Gibbons, Goderich; Lionel E. Shipley, Falkirk; and Stephen White, Charing Cross, Kent. The following were present *ex-officio*;—Professor Buckland, Professor of Agriculture, University College; Dr. Beatty, President of the Mechanics' and Arts' Association; and Mr. W. H. Mills, President of the Fruit-Growers' Association. Messrs. Edwin Mallory, Napanee, and Geo. McDonell, Cornwall, the remaining elective members of the Board, were absent. Mr. McDonell telegraphed to say that, owing to the storm, he would not be here before noon next day. Mr. H. C. Thomson, Secretary, acted as secretary to the meeting.

To allow time for the arrival of the absent members of the Council, the meeting adjourned till the day following, but before the members left the room, Mr. Mallory arrived, making only one absentee.

On the re-assembling on Thursday, Mr. Hugh C. Thomson, the Secretary, took the chair. No particular business was transacted during the morning, as it was deemed desirable to wait till afternoon for Mr. McDonnell. Mr. Christie, who had been nominated for President wished his name withdrawn, as he had determined not to become a candidate.

In the afternoon, after another adjournment, business was resumed, and Mr. Edwin Mallory having been elected President of the Council, took the chair. Mr. Lionel E. Shipley was elected Vice-President.

After considerable discussion, Mr. George Graham, of Brampton, was elected Treasurer, the salary being fixed at $400 per annum.

The Bank of British North America was selected in which to deposit the funds of the Association.

Mr. Rykert moved, seconded by Mr. McDonell, that four securities of $5,000 each, the Treasurer himself in security of $10,000, should be given by the Treasurer. Carried unanimously.

Mr. MacDonell moved, seconded by Mr. Rykert—That a new seal be procured for the Board. Carried.

The question of appointing a new Secretary was then brought up, and excited considerable discussion, but the motion to that effect, as well as another to postpone the decision, were lost, and Mr. H. C. Thomson was retained to fill that office.

Mr. Rykert moved that Messrs. Christie, White, Cowan, Mills and Dr. Beatty, be appointed a Committee to approve the Treasurer's security, and that they meet at the office of the Board on the 17th of March.

Mr. Christie moved, seconded by Mr. McDonell, that Professor Croft be consulting chemist; that Andrew Smith be veterinary surgeon and referee; that James Fleming be seedsman; that W. A. Cooley be general superintendent of the exhibition; that J. E. Pell be superintendent of the arts and manufactures departments; that J. Fleming and W. H. Mills be superintendents of the grain, roots, and horticulture departments. Carried.

At this stage of the proceedings, the minutes of the Board were read and approved of. The Secretary then read the Auditors' report.

The Auditors appointed at the Annual Meeting of the Agricultural Association of Ontario, held at Hamilton, in September, 1868, would first remark, that under existing circumstances, they have felt it their duty to allude to matters which occurred prior to the year 1868.

The classified account of receipts and expenditure, prepared by the Secretary from his books, and those of the Treasurer, together with the vouchers, will show,—.

The balance last audit to be..	$12,493 07	
The receipts	19,583 85	
Total.....		$32,024 52
The payments		25,110 88
Showing a balance on hand ..		6,908 14
The Treasurer brings down a balance in his books of....	559 14	
To which add two items twice charged.....	11 00	
		570 14
By adding the charge for commission made by the Treasurer in 1867.....		6,338 00
Making		$6,908 14

It will be seen the accounts so far agree.

Add to this,

Interest on renewals of Note, 1867.....	159 26	
Interest on renewals of Note, 1868.....	150 50	
Commission charged by Treasurer in 1868.....	800 00	
		1,109 85
These together.....		8,017 99
There is a Note held by the Bank of British North America against the Board, under the seal of the Board, signed by the President, Treasurer and Secretary.....		8,017 99
And, now under protest, for..	8,800 00	
Interest and Protest for 23rd February, 1869.....	143 86	
		8,943 86
There is also a balance left from the Paris Exhibition Fund, reported to us to be about.....		1,022 02
There is also a balance left from the fund given for the entertainment of the Maritime Guests, at London, in 1865, reported to be about.		300 00
These together make ..		13,283 87

Which sum remains in the Treasurer's hands, to be accounted for to the Association.

In the accounts of 1868, the sum of $1,600 is charged as Treasurer's salary; and in the accounts of 1867 $400 is charged, making together $2,000; which, by resolution of the Board, was appropriated to Mr. Denison, as Treasurer, for the years 1867 and 1868.

The Auditors, in charging the interest, as above, back to the Treasurer's account, do so believing that no such necessity existed as that of discounting a note; large balances appearing from year to year to the credit of the Association, and upon which no interest has been allowed.

The money given by His Royal Highness the Prince of Wales to be invested, the interest of which, from year to year, to be given in a prize or prizes, was lent to the late Col. Thomson, then President of the Board; the amount was £200 currency, or $800.

It bears interest at 8 per cent., which appears at the credit in account. We are informed that this is secured by a bond given by the executors of the deceased.

We would respectfully draw the attention of the Board to insurance on property. We are of the opinion that the Library should be insured; and it is a matter for the Board to consider, if a sufficient amount is insured on the Hall.

The farm property is insured in a Mutual Company; Mr. Denison, the Treasurer, being liable on a note for premium, for $48, upon which $4 has been paid and charged in accounts.

The certificate of the Secretary, as to the issuing of orders for payments, to the amount of $229, for which we had no vouchers, will explain itself. Since the certificate was made out Mr. Denison has produced receipts, and the butts of his cheque book showing all paid but five persons, the amount $27. We have not deducted this sum from the accounts. The Treasurer placed before us vouchers paid since the 31st December, 1868, amounting to $405 91; these are entered in the Treasurer's books, and certified to by us, and the vouchers handed over to the Secretary, but not included in the accounts.

JAMES JOHNSON,
THOS. D. HARRIS, } Auditors.

Toronto, 23rd Feb., 1869.

Our charge for audit is $122.

JAMES JOHNSON,
THOS. D. HARRIS.

The Auditors' Report was received, and the charge ordered to be paid. Before passing any vote on Mr. Denison's claim for $800 commission, it was resolved to request him to meet the Board on the following day.

Mr Christie said it had been an understood thing with Mr. Denison's Solicitor, that the item should be withdrawn. He did not see how then it appeared in the report. The Secretary explained, that in a conversation with Mr. Denison, that gentleman had disclaimed all knowledge of such an agreement having been come to by his Solicitor.

Dr. Beatty stated that the Board had all along distinctly repudiated the idea of Mr. Denison's right to charge any commission in any circumstances. When the idea was first mooted an augmentation of $600 had been made to Mr. Denison's salary, on the distinct understanding that the Board should bear no more of charges for commission.

The Secretary read a letter from the Poultry Association to the following effect:—

Sir—I have the honour to inform you that the Ontario Poultry Association have instructed me to communicate with the Council of Agriculture and Arts Association of Ontario on the following subjects:—

1st. That in reply to a deputation from the Ontario Poultry Association to the Commissioner of Agriculture and Arts, soliciting a grant of money in aid of the Association, they were referred by that gentleman to the Agricultural Association as a body, receiving from the Government a large annual money grant, a portion of which is appropriated to the same object as that for which the Poultry Association was formed.

2nd. That, in view of the many obligations already received from the late Board of Agriculture, the Poultry Association did not feel justified in making the application suggested by the Commissioner of Agriculture and Arts; nor do they now deem it prudent to solicit from the Council of Agriculture and Arts Association a direct annual grant.

3rd. The Poultry Association, however, desire to direct the attention of the Council of the Agriculture and Arts Association to the admitted fact, that, since their organization in the latter part of the year 1866, marked improvement has taken place in the specimens of poultry shown at the respective exhibitions—Provincial as well as local—held since that period; that such improvement is evident in the increased number and improved breeds of birds shown, the class of persons who have recently become exhibitors, the importation into the Province of breeds of poultry hitherto unknown therein, and generally the increased interest in poultry taken by a large class of persons hitherto indifferent to such matters.

4th. That this desirable state of affairs is chiefly attributable to the wholesome competition which has, under the auspices of the Poultry Association, lately arisen, and to the high standard of excellence adopted by the Association, whereby judges, in awarding prizes, are guided and governed, which standard, to the poultry fancier, cannot fail to contrast itself forcibly with the mode of judging and classifying fowls adopted at Provincial Exhibitions prior to the inauguration of the Poultry Association, and which at county and township shows still obtains.

5th.—In view of the foregoing facts, the Poultry Association respectfully submit to the Council of the Agriculture and Arts Association whether it would not be alike in the interests of that body, as in creating a still greater impetus to the importation and improvement of the breed of poultry in this Province, to transfer to the Poultry Association the entire control and management of the poultry branch of their annual exhibitions, with power to prepare prize lists, appoint judges, award and withhold prizes, and generally to conduct the details of that branch of the exhibition, in the same manner and under the same rules and regulations as those by which the exhibitions under their own auspices are guided and governed, and that the amount of prizes awarded, as well as other expenses incurred in respect of such exhibitions, be paid out of the funds of the Agriculture and Arts Association, together with an annual contribution of $——* towards the funds of the Poultry Association, by way of remuneration in attending to the duties above enumerated.

I have therefore to request that you will, as soon as convenient, submit for the consideration of that body the subject of this communication.

I have the honour to be, Sir,
Your obedient servant,
THOS. McLEAN,
Hon. Secretary.

Mr. Mills moved, seconded by Mr. Skead that a by-law be enacted appointing the President, Mr. Christie, Mr. John Walton, Mr. J. C. Rykert, and Mr. Cowan, to be an Executive Committee.

This by-law, after some discussion, was passed.

Mr. Rykert moved, seconded by Mr. Mills, that the annual exhibition be held on the 20th, 21st, 22nd, 23rd, and 24th of September.

Mr. Christie suggested that the Secretary should be instructed to notify the Agricultural Associations of Quebec, New York, Ohio, Illinois, and Michigan, of the time appointed for the holding of the Ontario Exhibition.

Professor Buckland suggested that the next meeting of the Board be held at London, as early in the Spring as possible. Agreed to.

Mr. Rykert moved, seconded by Mr. Wilson, that the Treasurer be authorized to pay such amounts, from time to time, as the Executive Committee may recommend. Carried.

Mr. Weld, of the *Farmer's Advocate*, was introduced to the meeting and urged the propriety of establishing an Agricultural Emporium, in which seeds could be collected and tested, and agricultural machines always at the command of the farming community. The whole subject was refered to the Executive Committee.

The Council adjourned till Friday morning at half-past nine.

The third day's proceedings commenced with the reading of the minutes of the previous meeting, after which Mr. Denison was introduced by the chairman, and proceeded to defend his claim upon the Association for commission. The substance of his statements is contained in the following letter written by him to the late President of the Board, and which he read :—"When making out my account this year I made a charge of one per cent. upon the money I received from the Government, and which I paid to the Riding Societies of the Province. This work I have performed for 15 years without any remuneration whatever. When I was elected Treasurer of the Agricultural Association the above was no part of my work, and it was not till some years after this extra work and responsibility was thrown upon me by an Act of Parliament. I have been relieved of the work which has been assumed by the Agricultural Department of Ontario, and I will venture to say the whole work will cost as much, if not a great deal more, than I have charged. When the subject came before the auditors, they said the charge was not at all in proportion to the responsibility and work.

When I first accepted the office of Treasurer to the Association (I was elected in my absence and without my knowledge), the work and everything in connection with it was in a far different state to what it is now, and has been for the last ten or fifteen years; yet there has been no increase in the salary attached to it.

The whole receipts of the Society in 1846 only amounted to $1,900, in 1847, $2,000, and in five years after, $8,000. It was in that year the Bill passed, under which I had to pay the Riding Societies $29,000 in addition to my other greatly increased work for the Association, in all $37,000.

The work has gone on increasing till now, when it amounts, as per the last completed audit, which was December 21st, 1866, to $81,449, made up as follows :—

Received on account of the Board	$ 5,265
Riding Societies	49,167
Associations	27,017
	$81,449

On these grounds Mr. Denisons' adhered to his claims for commission. In reply to an enquiry whether the matter could not be arranged by arbitration, he said that he did not like arbitration, and finally it was resolved—

That after hearing the explanations of Mr. Denison, and the old members of the Board, this Board is of opinion that the charge of the late Treasurer for commission should not be allowed, and that unless the money be paid over to the present Treasurer in one month, or security given, satisfactory to the Executive Committee, legal proceedings be taken to recover the same.

Mr. Rykert moved, seconded by Mr. Christie--That a special Committee, consisting of Messrs. Dr. Beaty, Macdonell, Graham, Christie, Cowan and the mover, be appointed to examine into and report to this Council upon the claims of the Association to the several Palaces and buildings in Toronto, London, Kingston and Hamilton, and the securities, if any, held by the late Board upon the same—Carried.

Moved by Mr. Rykert, seconded by Mr. Macdonell—That the Secretary and Treasurer be instructed to insure the Library and Furniture of the Association in some Stock Company for a sum of not less than $2,000. —Carried.

Moved by Mr. Rykert, seconded by Mr. Christie—That the Secretary be instructed to notify the Secretary of the Poultry Association, that their communication will be referred to the Executive Committee for their report.

Mr. Christie moved a By-law to the effect—That the Treasurer shall, as soon as convenient, deposit in the bank of the Association all moneys received on its behalf; that the Treasurer shall keep a deposit account of silver received on behalf of the Association in such bank. That the Treasurer shall, at the end of each month, prepare a statement of the receipt and expenditures of the Association, and publish the same in the agricultural journals published in the Province of Ontario. That there shall be two financial periods, namely, the 30th day of June and the 31st day of December in each year; and at the expiration of each period it shall be the duty of the Treasurer to prepare and submit for audit his accounts for such periods. That immediately on the preparation of such statement, it shall be the duty of the Treasurer to summon the Auditors to examine his accounts, and when the Auditors shall have made their report, the Treasurer shall publish the same in the agricultural journals aforesaid.

This by-law was read a first, second and third time, and passed.

Mr. Rykert moved, seconded by Mr. Gibbons, That Messrs. Patton, Osler & Moss, be appointed by the Board as their solicitors. —Carried.

It was moved by Mr. Rykert that the Secretary notify the Commissioners of Agriculture of the Treasurer's appointment.—Carried.

Dr. Beatty moved that the Treasurer's securities be referred to the Executive Committee in lieu of the Special Committee, and that the settlement of the valuation of the farm property be referred to the Executive Committee, and that the Secretary be instructed to employ Mr. Sheard to value said farm as soon as practicable.

A letter was read from Mr. Donaldson on the growth of flax. The letter was laid on the table.

Moved by Mr. White, seconded by Mr. Gibbons, that the next meeting of Council be held at London.—Carried.

Professor Buckland asked for the annual grant of $40 for the defraying of the expenses of the examinations at the Veterinary College.

Mr. Christie cordially supported the grant. There was no more useful institution connected with the agricultural interests of the country than the Veterinary College. In olden times, a properly qualified Veterinary Surgeon was a thing unknown, and the losses that fell on the farming population for lack of them was incalculable. Now, however, this desideratum was being speedily supplied by means of this institution. He regarded Professor Smith as able a man in his profession as was to be met with on the continent. In Illinois last year he had ample opportunity of comparing him with Professor Gamgee, and it appeared to him that Smith was the abler man of the two; and they ought to be proud of having such a man connected with the association in any way.

Mr. Cowan also spoke in favour of the grant.

Mr. Gibbons asked how many graduates the College had sent out? He put the question as he had not come across any of them in his district.

Prof. Buckland replied that already sixteen certified surgeons had been sent from the College, and at present the number attending the classes was twenty-five. Another point he called attention to was the want of accommodation for the proper carrying on of the classes of the College. The premises were altogether unfitted for the proper management of the College, and he thought it would be advisable at some early day for the Board to accept Professor Smith's offer, viz, that he will build proper premises if the Board guarantee him the sum of $150 per annum. Mr. Buckland then referred to the great importance of experiments being carried on, and enlightened views disseminated concerning the improvement of their classes of wheat. It was all very well to have shows of cattle, &c., but no matter of greater moment could possibly be brought under the consideration of agricultural associations than this. He then read the following letter from Mr. Arnold, Paris, bearing on this subject :—

"Paris, Ontario, Feb. 6, 1869.

"Hon J. Carling, Commissioner of Agriculture :

"Sir,—Having been impressed for many years with the importance of hybridizing or crossing different varieties of fruit, and having proved by my experiments with the grape and the raspberry, that with both these fruits, vigour and productiveness have been very much increased by crossing; the idea became strongly impressed on my mind that the judicious crossing of different varieties of wheat must be attended with like beneficial results. Acting upon this suggestion (and I believe also a desire to benefit my country), three years ago I selected one plant each, white Soules and red midge-proof wheat, and after much persevering labour have succeeded in producing 15 varieties (selected from upwards of 100) that seem to combine all the good qualities of both parents with much increased vigour and productiveness. One variety in one season yielded me upwards of 4,800 kernels from one kernel; and last year, under ordinary cultivation, some of these varieties yielded at the rate of from 60 to 80 bushels to the acre, while other varieties in rows, within 7 inches of them, under the same cultivation, only yielded at the rate of from 20 to 30 bushels per acre.

These wheats were partially examined last year by Hon. D. Christie, but more thoroughly by P. O'Connor, Esq., Hiram Capron, Esq., and Mr. Edward Brown, all good judges.

"I have now about an acre of these 15 varieties planted, and solicit from the Agricultural Association a most thorough investigation of their merits, believing as I do that they will prove of more value to this country than any new wheats imported from England or anywhere else.

"Your obedient servant,
"CHARLES ARNOLD."

Mr. Christie and other members of the board, spoke in high terms of the efforts Mr. Arnold had made in this direction, and the remarkable success that had attended his experiments, adding that it would be well in some tangible way to recognize the services of men like Mr. Arnold, who spent so much time and money in improving the produce of the country. It was stated that, in all probability, unless the Association obtained a quantity of Mr. Arnold's varieties of grain at once, they would not get it at all, as several Americans had an eye on his experiments, and were prepared to purchase the results at any price.

Mr. Christie, as one of the deputation to the Illinois Convention, stated that as a full report of the proceedings was being prepared in New York, they had not thought it needful to prepare any formal report. Whilst at the Convention, his attention had been particularly called to the Texan fever among cattle. A great many notions were afloat with respect to this disease, nearly all of which were absurd. Some maintained that frost was a preventive, but this was untrue. Others averred that Texan cattle could not be ill. He himself had seen a fine sleek Texan steer killed, and when the stomach was removed there were found a great number of ulcers healed up, and many fresh active ulcers, showing not only that Texan cattle were obnoxious to the disease, but that the disease itself was sometimes long continued. The disease was more of a sporadic character than epidemic. This had been distinctly shown by some experiments made with rabbits. Portions of the fungi had been spread on pieces of apples. The rabbits ate the apples thus prepared, and died of genuine Texan fever. This experiment showed how easily disease might be carried from one place to another. And he could give one instance illustrative of this. Last summer, thirty cattle died at Paris. The symptoms exemplified were similar in each case, and entirely different from those characteristic of any known disease. In fact, the symptoms were those of Texan fever; and from the fact that the disease in this case originated in proximity to the Grand Trunk, he had not the slightest doubt but that from the excrements of the cattle in trucks the disease had been dropped there. He at once applied to the Government to prohibit the importation of American cattle. His suggestion was carried out, and fortunately the plague was stayed. The object of the Convention was to investigate into the nature of the disease; and the result to obtain, if possible, uniform legislation relative to the transit of cattle. Several States were already moving in the matter, and the sooner the Province of Ontario took the matter up the better; and the Board should at once memorialize the Government on the subject. It was an awful, fearful scourge, when it had once obtained a footing in a country; and efforts should be put forth to render such a visitation as near to an impossibility as possible.

Dr. Beatty moved that in reference to the communication from Mr. Arnold, on improvement of seeds, that the members of the Executive Committee be instructed to supervise the operations of growth and mode of improvement, so far as opportunity allows, and that a special prize be offered in the prize list for any such efforts as shown by the Grain Grower. Carried.

The business of the Council being now over, the Chairman said that now he had for the first time an opportunity to thank them for the high honour they had done him in putting him in the honourable position of President of the Council. He then expressed the change which his sentiments had undergone in reference to the members of the old Board, whom he thought had been much maligned. He spoke warmly in their favour, and was heartily sorry for the rashness with which he had judged them.

The Chairman's remarks elicited a very angry rejoinder from one member of the Board, and the proceedings terminated in a very stormy and unseemly manner.

Fifteen million bushels of grain were handled at Toledo in 1868.

In three years a farmer on the Isle of Man raised seven bushels of barley from a single grain.

Sale of Thoroughbred Stock.—Mr. Joseph Kirby, of, Milton, Ont., sold, February 13, 1869, to Mr. Cowan, of Guelph, the young bull Marlborough Duke, out of Young Countess, by Duke of Marlborough, 5587, A. H. B., the heifer Pride of Esquesing, out of Mountain Daisy, by Butterfly 2nd, 91, C. H. B. To Mr. Waters, Eramosa, bull Young Marlborough, out of Countess 1st, by Duke of Marlborough, 5587, and heifer Maid of Marlborough, out of Mary, by Duke of Marlborough. To Mr. Rawson, Pusilnch, the heifer Lady Grant, out of Louisa, by Duke of Marlborough; and heifer Lady Grey, out of Miss Miller, by Duke of Marlborough. All the above animals are under one year old.

Wool Growers' Meeting.—The New York State Wool Growers' Association, held its annual meeting at Syracuse on the 27th of January. The attendance was large. The chief business, besides the election of officers, was the consideration of the feasibility of holding a wool exposition during the year, a question ultimately referred to a committee, and the discussion of a new reciprocity treaty with Canada, against which the meeting unanimously and urgently protested. Such a measure, in the opinion of American wool growers, was horrible to contemplate, would at once arrest the stream of emigration to the States, and indefinitely augment the population and prosperity of Canada; for, to quote the concluding sentence of one of the resolutions :—"With their cheap living, low taxes, and consequent low-priced labour, and with their good soil, the Canadas could multiply their productions to an indefinite extent, if we were to give them the benefits of our markets, where high prices must prevail as long as high taxes last." Let us be thankful for our advantages. As regards this question of reciprocity, we are satisfied that the abrogation of the treaty has hurt our neighbours more than ourselves, and that sooner or later a free interchange of commodities without restrictions will be resumed, to the mutual advantage of both countries.

"CANADA FARMER" Office, March 12th, 1869.

FLOUR AND MEAL.

The market has been quiet and dull, without actual decline in prices, which may be quoted as follows:

Flour—No. 1 Superfine, $4 to $4 05.
Oat Meal—$5 75 to $6
Corn Meal—$3 50 to $3 75.
Bran, per ton—$16.

GRAIN AND SEED.

Wheat—There is very little doing on the street market. Notwithstanding the sleighing being good, only an occasional load of wheat is to be seen on the market square. The following are the prices: White fall, 92c.; red midge proof, 91c. to 95c.; spring wheat, 93c.

Oats—Market quiet and dull. 50c. is the highest price that was paid for a lot; on the street market 51c. to 52c. was to-day paid for a few loads.

Barley—The market has been dull and drooping. To-day not over $1.30 could be got for good samples in car lots, and the demand was light at that price. Street price $1.30 to $1.32.

Peas—The market has declined. No car lots have been changing hands. On the street market there were fair receipts during the past few days. The street prices range from 75c. to 80c.

Rye—Selling on the street at 65c.

Clover—Dealers are buying at from $6.70 to $7.

Timothy—Dealers are buying from $2.25 to $2.75.

Hungarian Grass.—Worth $2.

Flax Seed—Worth from $2 to $2 50, according to quality.

Tares—Dealers are buying at $1.75.

PROVISIONS.

Pork—Mess is scarce and held in few hands; sales have been made at from $26 to $27 per barrel.

Bacon—From 10c. to 12c.

Hams—From 12c. to 14c.

Cheese—From 14c. to 15c.

Butter—From 20c. to 30c.

Eggs—From 15c. to 20c.

SALT.

American selling at $1 50 in barrel. Canadian at $1.60.

THE CATTLE MARKET.

Beeves—The market has been better supplied than of late, and the cattle offering were generally good. In fact there were few or no third-class cattle to be seen. Selling at from $5.50 to $7 per 100 lbs.

Sheep—There were not many offering and there was a good demand. Prices have slightly advanced.

1st class.....$7 00 each.
2nd class..... 4 50 to $5 00

Calves—There was a fair supply offering, and a good demand. 1st class calves brought from $9 to $10. 2nd class, $6, and 3rd class, of which there were a good many, from $3 to $4.

HIDES AND WOOL.

Hides, from 6½c. to 8½c. *Calfskins*, green 10c.; dry, 18c. to 20c. *Sheepskins*, 40c. to $1.60. *Wool*, 25c. to 30c.

HAY AND STRAW.

Hay—Market has been well supplied, and prices have advanced. To-day the prices paid were from $14 50 to $15.

Straw—Fair receipts. Prices ranged from $5 50 to $7.

London.—*White Wheat*, $1.06 to $1.16; *Red Fall Wheat*, 85c. to 90c.; *Spring Wheat*, 90c. to 97c.; *Barley*, $1.20 to $1.30; *Peas*, 70c. to 80c.; *Oats*, 45c.; *Corn*, 65c. to 69c.; *Hay*, $9 to $10; *Potatoes*, 50c. to 55c.;

Hamilton.—*Wheat, White Winter*, $1 to $1.05; *Red*, 95c. to 97c.; *Spring*, 90c. to 95c.; *Peas*, 65c. to 85c.; *Oats*, 51c. to 52c.; *Barley*, $1.20 to $1.25; *Clover Seed*, $6.75 to $7; *Timothy Seed*, $2.50 to $3; *Turnips*, 20c. to 25c.;

Montreal Markets. Montreal, March 10.—*Flour*—No. 1 Canada Wheat, $4.50 to $4.55; No. 2 Western Wheat, $4.20 to $4.30; bag flour, 100 lbs., $2.15 to $2 25. *Wheat*—Spring, $1 09c. to $1 10c.; *Oats*—Per 32 lbs., 00c. to 00c. *Barley*—Per 48 lbs., $0 00 to $0 00.

JUCUNDA

STRAWBERRY PLANTS

FOR SALE.

THE undersigned will sell plants of this very valuable berry at the following rates:

By Mail, post-paid, 50 cents per Dozen.
Do. do. $2 per 100.
Delivered at Express, $10 per 1,000.
Do. do. $75 per 10,000.

Wilson's Albany, 75c. per 100, $4 per 1,000; Triomph de Gand, Russel's Prolific, Brooklyn Scarlet, Metcalf's Early, $1 per 100, $5 per 1,000.

SALEM GRAPE VINES.

The undersigned has also been appointed agent for the sale of Salem grape vines propagated from the original stock purchased of Mr. Rogers, who pronounces it the best of all his Hybrids, which are becoming the most popular grapes in America. The grape is of a light chestnut or catawba color, free from hard pulp, very sweet and sprightly, with a most exquisite aromatic flavor; as early and hardy as Delaware or Hartford, having never failed to ripen its fruit during the last six years. It took the first prize (quality to rule) at the Lake Shore Grape Growers' Association, held at Painesville, Ohio, last season, in competition with all the leading varieties of that famous grape region.

PRICE OF 1ST CLASS VINES:

	EACH.	PER DOZ.	PER 100.	PER 1,000.
1 year-old.....	$1 00	$6	$35	$250
2 years old.....	1 50	9	50	350

Vines post-paid by mail at the price per single vine. Carefully packed and delivered at express at the other rates, and warranted genuine.

THE TWO BEST EARLY POTATOES,

SELECTED FROM GENUINE STOCKS.

EARLY ROSE.—The Early Rose is a seedling of the "Garnet Chili" originated by Albert Brewer, Esq., an intelligent farmer of Varnum's. The skin is of a dull blush or rose color (in some soils nearly white,) the flesh perfectly white and solid, and the eyes very shallow. It produces fewer small tubers than any other early potato, boils through quickly, and is very mealy, and of excellent flavor. The good qualities which recommend it are—

1st. It is from ten days to two weeks earlier than any other Potato.

2nd. It is of larger average size than any other early Potato.

3rd. It is in table quality and delicacy of flavor without an equal.

4th. It is in productiveness the most astonishing variety ever offered to the public, and the reports of the yield from single pounds the present season are marvellous.

PRICE.—One pound, 75c.; do., postage pre-paid, $1; one peck (15 lbs.,) $6. Larger quantities furnished at reduced rates.

EARLY GOODRICH.—This variety was introduced a few years ago by the Rev. Chauncy E. Goodrich, of Utica, N.Y., who spent fifteen years in experimenting on the production of new varieties, and in that time raised over sixteen thousand seedlings, and the Early Goodrich was considered by him the finest of his whole productions; it is very early, of large size, white skin, smooth eyes, white flesh, of first-rate quality, and always perfectly solid—per bushel $2; per barrel, $4.

In addition to the above we have to offer several other varieties of very choice SEED POTATOES. For description and prices see our DESCRIPTIVE PRICED CATALOGUE, a copy of which will be mailed to any address on receipt of a three-cent stamp to pre-pay postage.

IMPORTANT TO FARMERS.

LAMB'S
SUPER-PHOSPHATE OF LIME,

$40 PER TON.

NO CHARGE FOR BARRELS, AND DELIVERED FREE AT RAILWAY STATION, TORONTO.

FARMERS

Sometimes complain that SUPER-PHOSPHATE costs too much to use.

FARMERS—IT SAVES LABOR, IT COSTS LESS PER ACRE THAN STABLE MANURE,

If you take the time in hauling Stable Manure, and spreading it out. But suppose it did cost more, it is 100 per cent. better.

FARMERS—Do you not think 25 per cent. a good Investment?

LAMB'S SUPER-PHOSPHATE OF LIME

WILL PAY MORE THAN 100 PER CENT.

WE PUBLISHED LAST MONTH A LETTER FROM A FARMER WHO SAID HIS

HAY CROP WAS TREBLED WHERE HE USED SUPER-PHOSPHATE OF LIME.

DOES THIS PAY?

And also another letter from a gentleman in Guelph, to the CANADA FARMER, that at an outlay of $7.50, he got

625 BUSHELS OF TURNIPS TO THE ACRE

Where he used Lamb's Super-Phosphate of Lime. In the field that he used no Super-Phosphate on he only got 360 bushels per acre, showing a net gain of **265 Bushels per Acre**, at a cost of $7.50.

FARMERS, DOES THIS PAY?--IT DOES PAY.

Last year, in February, we sold to one Farmer $667 worth, and in May he ordered another large lot, and we could not send it, as we had sold all out, and received a great many orders after we had sold our stock. In consequence, this year we have manufactured a larger quantity of a very superior quality, and trust that we shall have enough for all; but do not delay in ordering, but order at once to insure to have it fulfilled. It is good for

WHEAT,	BUCKWHEAT,	CORN,	CABBAGE,
RYE,	MILLET,	BEANS,	ONIONS,
OATS,	BARLEY,	PEAS,	POTATOES.

—ALSO,—

TURNIPS,	BEETS,	CARROTS,	MANGEL WURTZEL,	CUCUMBERS,
		STRAWBERRIES,	TOMATOES.	

FOR FRUIT TREES, RASPBERRIES, CURRANTS, GRAPE AND HOP VINES,

Ground Bones are an invaluable and lasting Manure. When the Trees or Vines are first planted, a liberal supply of half inch Ground Bones should be used about the roots, and Super-Phosphate applied as a top-dressing. In spring loosen the earth, and apply liberally, raking it in. This will give a vigorous and healthy growth, ripening the wood early, and causing a larger amount and more luxuriant growth of fruit; also, improving the quality.

CASH TO ACCOMPANY ALL ORDERS.

The Field.

Liming Land.

The application of lime to the land in greater or less quantities is a very common practice in Britain, though but little followed in this country. Considering how cheaply the article can be produced, and the lasting good effect of applying it to the soil, it is a matter of considerable surprise that the practice of liming land is not more general with us.

The properties to which lime owes its chief power in promoting vegetation are twofold. It is an alkali, or rather alkaline earth, that acts as a solvent on many vegetable acids by combination, forming with them a compound soluble in water, and thus more readily taken up by the roots of plants. Thus, on soils containing a large amount of humus it proves extremely beneficial. It is more porous than clay, and has therefore a mechanical effect in rendering clayey soils more friable and workable, as well as being of a manurial value in assisting the decomposition of the vegetable salts in the soil. This is termed correcting its acidity. Wheat and mangoids contain a considerable proportion of lime in their composition, which accounts for the necessity of having sufficient lime in any soil to ensure good crops of wheat or mangolds.

Lime acts most quickly and powerfully when used in its caustic state, in the form of quicklime, and applied in this form to the soil, especially to one abounding in vegetable matter, it soon acts, and reduces the half-decayed weeds and roots into soluble plant food. Hence the value of quicklime when applied to fallows or clover leys a week or so before wheat-sowing.

But lime in this state usually requires great care in handling, or injury to the person using it may result, and so the most general way of applying it is in the milder state of slaked lime.

The best time to apply lime is either in early spring, on the land after ploughing for spring crops, and before it is harrowed down preparatory to seeding, or in the fall on sod land that has been just broken up, to be followed by roots or corn. The lime will then have time during the winter season to decompose the roots of the grasses, weeds, etc., in the soil.

There are some soils that already contain sufficient lime for all practical purposes. These are usually called limestone soils, and overlie the limestone formation of rock, or have gravelly or shaly limestone in their composition.

As lime contains but little, if any actual elements of fertility, but rather acts as a solvent or digester of those already in the soil, its tendency is to cause the soil to become more quickly exhausted of its fertile salts, by enabling larger crops to be grown, unless they are returned to the land in the shape of organic manures. On soils that are poor, or have been already over-cropped and exhausted of these organic matters, the application of lime will be of no benefit whatever.

For the same reason, when once lime has been applied, if the land is still kept well supplied with organic matters through the use of barnyard manure, etc., it is well to renew the liming once every few years, if the greatest degree of productiveness is desired.

The quantity of lime that can be usefully applied to the land depends much upon the quality of the soil. The richer and heavier the soil the greater may be the quantity given.

In England it is no uncommon thing to apply a dressing of three hundred bushels per acre, while the average rate may be estimated at one hundred bushels per acre. In France it is more commonly applied annually, in smaller quantities of from five to ten bushels per acre. This last plan would probably be most applicable here, as our system of tillage is like that of France, somewhat too shallow, and as lime naturally sinks into the soil after a time, a heavy application all at once, at intervals of ten to fifteen years, would soon settle down to the hardpan, and become inoperative before half its work was accomplished.

Lime needs to be applied evenly over the surface, and when both the lime and the weather are dry; otherwise it will run into lumps before it can be mixed with the soil.

Soils that are wet, or subject to retain surface water, will gain no benefit from the application of lime, unless they are first drained.

Culture of Sugar Beets.

Mr. James Howard, M. P., in his report on European Continental Agriculture, gives an interesting account of his visits of inspection to several large growers, and manufacturers of Beet Root Sugar in France, Belgium and Germany. This portion of his paper, as stated in our recent notice of it, we reserved for future consideration, and now give an extract on the practical point of culture and management of sugar beets.

At Cologne he visited a large concern known as the Rhenish Beet Root Sugar Company, that in addition to the roots grown on a farm of their own of 7,200 acres, purchase large quantities of beets from the surrounding farmers at 20s. per ton, the pulp being returned to them free.

This firm has issued printed instructions for the guidance of the farmers, which translated into English are as follows:

"1. In order to grow good sugar beet it is necessary that the land intended for the roots

should be ploughed at least 10 inches deep before winter; as the frost renders the soil as fine as ashes, it enables the farmer to work the land readily in the spring, and the rapid growth of the plant is greatly facilitated. 2. From experience it is proved that roots planted in ground freshly manured, either with farm-yard dung or compost, suffer from unequal growth and various kinds of insects. The quality also, in most cases, is inferior. It is better, therefore, to highly manure the previous crops and avoid the direct application of manure to the beet field. 3. As soon in in the month of April as the land has become sufficiently warm (say 45 to 50 deg. Fahrenheit) the sowing of the seed should commence, for according to all experience, the earliest planted beet are always the best. Drilling in all cases is to be preferred to sowing by hand. The cultivator should always bear in mind that the soil would be as fine as meal, yet not too loose, so that the seed is not deposited too deep. 4. If sown by hand, the roots should be in 14 inch squares; within the radius of the Cologne fortification, a rich district; the rows should be 12 inches wide and the roots 8 inches apart, so that they do not become too big. If drilled with a machine, the distance should not exceed 15 inches, and thinned out at 10 inches. 5. As soon as the plants are visible, hoeing between the rows should commence. The growth of the weeds is thereby checked, and also, the ever-forming crust which shuts out the air, is broken, and insects and vermin are destroyed. When the plants have six leaves the thinning or singling out should be begun. Frequent hoeing subsequently is also necessary to keep the land from becoming bound. When, in the month of July, the heads of the roots show above ground, which heads are totally useless for the sugar manufacturer, their development must be checked by moulding-up, which operation also facilitates the getting up of the roots when ripe. 6. Leaves are to a plant what lungs are to an animal; therefore, nothing damages the beetroot more than taking off the leaves before harvest. Such a senseless course reduces the value of the crop one-half. 7. Roots, which are to be kept for several weeks or perhaps months, before being taken to the factory, should be quite ripe when gathered, should not have been exposed to frost, and should have been harvested in a fresh or moist condition. The roots are seldom ripe before the middle of October, yet frequent frosts occur at the beginning of November; the beetroot cultivator must, therefore, make haste to harvest his crop before the frost commences, and postpone all other work until the crop is secured. If a long drought has occurred, the growers should wait until a good rain has fallen, for roots that are harvested in dry weather, and after a long drought, will not keep. 8. The raising of the roots is best performed by means of spades or shovels; forks are not suitable for this operation, for, from experiment, too many roots get pricked, and pricks are a certain cause of decay, whereas a smooth cut with a shovel is not so injurious. In any case, however, wounding of the roots must be most carefully guarded against. 9. The leaves of the gathered roots should be cut off with a sharp knife close to the crown, also the under leaves, which in most cases are decayed, must be removed by the hand or the knife, because they induce rottenness, and if left on are troublesome during the washing process. 10. Roots which are to be conveyed to the factory within three or four days of gathering should be plentifully covered with leaves, because the sun's rays beget decay of the roots, and rotten roots produce dark coloured juices, which are valueless. If the roots have to be taken to the factory later, they must be thoroughly well covered with earth either in pits or heaps, so as to protect them as well from the heat of the sun as from the frost, and thus prevent their losing quality or quantity. The beet root cultivator should remember the well-known proverb, 'Out of the earth, into the earth,' i. e., the earth not only produces but preserves. 11. The pit or heaps should be 3 feet wide, and I spit deep, and of any convenient length. The roots should be laid with the heads outwards. The work of covering up as well as the removal to the factory should be carefully performed, so as to avoid the bruising or wounding of the roots as their soundness is of the utmost consequence. Heaps which are 3 feet wide should not be more than 3 feet high, so as to keep the roots cool and prevent their sprouting. The roots should be covered up *immediately*, with at least two feet of earth, in order to avoid thoroughly the admission of air, for every change of temperature is injurious to the roots. Ventilation by straw chimneys or other methods must be most strictly avoided. If the heaps cannot be completed before night, a thick layer of leaves should be used as a tempory covering to prevent damage by night frosts. 12. In carting the roots to the factory, great care must be taken against bruising or breaking off the tap-root (the tap-root is the richest in sugar), for roots handled roughly soon show black spots and quickly rot. 13. That the foregoing rules are attended to properly, the inspector appointed by the sugar factory will satisfy himself from time to time by actual observation."

Mr. Howard says: "If I do not mistake, these rules contain matter for reflection, and may suggest to the thoughtful English farmer some useful lessons in the cultivating and harvesting of the ordinary mangold crop. The processes pursued in the sugar factories of the Continent are very simple. The roots, being first washed in a machine, are dried and pulped; the juice pressed out by hydraulic machines, followed by the usual refining process. At the great manufactory I have referred to at Cologne, at which 150 tons of beetroot are converted into sugar daily, the process of extracting the sugar is unique, and far more perfect than any other factory I had the opportunity of inspecting. Indeed, the whole arrangements are complete. Every department was thrown open to me, and every process explained, without the least reserve. When the last portion of the factory was finished, a carriage and pair, belonging to one of the partners, was politely placed at my disposal for a drive round their extensive farm. To return, however, to the sugar-making: Instead of extracting the juice from the pulp by pressure, as is the general practice, the pulp is put into a kind of colander, placed inside of a cylindrical vessel; when filled, the colanders are put in action by the steam-engine, and a rapid rotary motion is imparted to them. The juice is thereby thrown off by centrifugal force. The result of this plan was said to be that two or three per cent. more sugar was obtained than could be extracted by the process of pressing. In Prussia the manufacturer has to pay the Government duty of 14s. 6d. per ton on the roots, instead of 17s. 8d. per cwt. on the sugar, as in France. The Prussian maker has, therefore, a greater inducement to extract every particle of sugar. This arrangement, again, has led the German cultivator to be much more particular in the choice of his seed. The best description I met with is the "Improved Vilmorin," propagated by M. Louis Vilmorin, of Paris, who claims to have had recourse to the process of selection and the establishment of pedigree in plants long before Mr. Hallet was heard of. M. Vilmorin informs me that the Vilmorin beet is more highly prized in Germany than in France, and accounts for it by the fact of the duties being levied in the different manner I have described. The refuse of the beetroot after the sugar has been extracted forms an article of cattle food, and is held in high estimation. About eighteen to twenty per cent is the proportion of pulp left; the worse the quality of roots, the smaller the quantity of pulp. It is preserved in deep pits, generally bricked like a grave—very often the expense of bricking is avoided—a covering of earth is laid upon the top. The pulp is generally consumed within the year; but if well covered up it can be kept sweet and good for two years, or, as I was assured, even for three years.

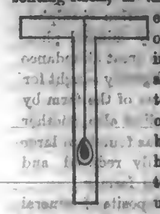
"Much controversy has taken place both as to the relative value of pulp as feeding stuff and as to its real money worth. Many practical men maintain that a ton of pulp is equal in value to a ton of roots. I think the money worth is best settled by the price it fetches. The average price at the factories I visited will amount to about 13s. per ton. Although horses do not like it, bullocks, which cannot be fattened on the root alone, can and are sometimes fattened for the English and foreign markets, without any other food than the pulp. Pigs do well upon it when cooked. Sheep will eat about twelve pounds a day of raw pulp. It is unquestionably more easily digested than the root itself; but cows kept upon it are said not to produce much milk. I was fortunate enough to obtain a debtor and creditor account of a sugar factory upon the continent, the locality of which, for obvious reasons, I am not at liberty to indicate. The proprietor is a large farmer. In it between 13,000 and 14,000 tons of roots per annum are made into sugar. The total expenditure, exclusive of the interest upon the money embarked, was £19,500, the total receipts about £33,000, leaving over £13,000 for profit and interest of money invested."

Practical Drainage.

BY ALAN MACDOUGALL, C. E.

As so much has been said about fall for drains and fall for water, it is necessary, now, that a few words of explanation be given, to show how the difference in level between two parts or points in a field may be ascertained. However true and regular the surface of the land may appear, the drainer, in attempting to follow that surface line with his drains cannot avoid having ups and downs in them. It is here the water lodges, and by not getting away, completely prevents air from coming up the drains and allowing them to work properly. It is very desirable, and should always be borne in mind, that the trench for the drains should have a regular grade, not be up and down anyhow, so long as the mouth is lower than the top.

To be able, therefore, to find out how his drains are to be laid, to work perfectly, the drainer needs some kind of a level, or instrument to help him take observations. The simplest thing that can be devised, and the one most readily presenting itself, is the *boning rod* already



explained. Two pieces of board, three or four inches broad and half an inch thick, are nailed together in the shape of the letter T, care being taken to have the head perfectly square to the body, which is usually about three feet long. Down the centre of the body a black line is drawn, and near the bottom a hole is cut to allow a plummet to hang. When the string of the plummet cuts the line, and the bob hangs freely, that is, is not resting on the body of the T, the head being placed at right angles to the body makes a perfectly level line, as level as it could be made by a carpenter's spirit level. It is not easy to sight along the top edge of the T, so it is well to have a sight nailed on to each end, and made to project from the side about two inches. They ought to be exactly level with the head of the T, or else, when a sight is taken on the presumed level line, it will in reality be on a grade.

The operator having got his borning rod into adjustment, can easily hold it quite straight, so as to keep the string of the plumb bob on the centre line. He then has only to send his assistant with a staff to any point whose level he wants to know. By looking along the sights, he can see where the line will cut the staff, and taking the difference in height of the reading on the staff and the height of his eye, or the top of the T, above the ground, he can find out whether the land rises or falls in that distance, and how much. It is very convenient, however, to have a rod graduated with feet and inches, of any convenient length, say six or eight feet, with a large target to slide on it, coloured in opposite quarters red and white. This can easily be seen by the eye, and with very little practice any one will be able to work with considerable accuracy. When the correct level has been got, the target is tightened by means of a thumb screw at the back of the staff, and it can be kept in that position until the operator comes up to measure the difference in height.

This is the readiest and simplest form of a levelling instrument. There are one or two others, which will be explained in the next paper, but the method of going to work is exactly the same in every case, and the method now explained is very simple. Any one can get this level, to give it a dignified name, made by any carpenter, or, indeed, make it for himself, and if it gets broken, the cost of repairing it is so trifling as not to be felt.

Hedges and Mice.

To the Editor.

Sir,—It is with great pleasure that I have read the late articles upon "Making Hedges" in your paper. The difficulty is not, I think, so much in the growth of the live hedge, but in the preservation of the fence when the whole of the obstacles towards a fair start have been overcome.

Now, it has been well shown in the articles to which I allude what kinds of plants grow the fastest or the best, which are most impervious, and which withstand best the frost, but there is a worse enemy than all these, namely, the ravages of mice. I was speaking to a gentleman the other day upon this subject, and he mentioned a case which came under his observation a few winters ago. A very fine hedge of thorn (I think he said the English thorn) had been planted and carefully attended to until it had formed a fence perfectly impervious to the attacks of the most evil disposed of breachy animals.

After much labour, time and money had been expended upon this hedge, and just as it had arrived at perfection, in one winter every plant was cut off by the mice, each stalk having been completely peeled from six to eighteen inches from the ground.

Now, such a case as this discourages many from attempting to substitute the beautiful hedge for the slovenly snake-fence. I have written, Sir, simply to draw from some of your staff, or readers, such experience as may show any easy method of preventing the ravages of these animals, or what kinds of plants seem to be most free from their attacks, thus hoping to provoke discussion, and call forth the opinions of those who have made experiments with live fences, upon this point.

C. E. W.

Ancaster, February 21st, 1870.

What has Science done for the Farm?

This is a question constantly and sneeringly asked by persons who pretend to dispute Book Farming, and who say, "I know all that twenty or fifty years of my experience can teach; I do as my father did, and so far as I can see my land is as good now as it was in my father's time, and I don't want to be troubled with "book farming."

There are thousands of such persons as these, and certainly book farming is very little use to them, for they have not the intelligence to make use of it, and yet these very people are the first to say when a crop fails, "times are not as they used to be, we had always good crops then."

The science of farming, and science in farming, has been more attended to in Britain than any place else in the world, and the consequence is that the average of the wheat and other grain crops has been within the last twenty years more than doubled, in some cases, and nearly doubled throughout England and Scotland.

Science in the first place went too far ahead of the times, the people could not understand it, and as the theorists who advanced the scientific assertions were not sufficiently practical, they could not always enforce conviction on the minds of their hearers and readers. Science first began to analyze the crops, and thus ascertained of what chemical elements they consisted. Then they analyzed the land, and prescribed as to what was required to render it fertile. Now, for want of material knowledge, the scientific people often went wrong, and every mistake was scored up against them, and widely blazoned abroad, while their successful hits

were confined to the parties benefited, and by them kept as quiet as possible, lest the landlord of a farm, if he found his tenants getting extra crops, should charge an extra rent, and thus get the benefit, or a larger share of the benefit than the tenant felt inclined to give him.

It was thus the interest of the scientific person to make his discoveries known, because it brought him customers, but it was the interest of the benefited farm tenant to keep the results as quiet as possible, and to prevent his success becoming public.

Of course but few believed the scientific theorist; it was his interest to make the most of his own discoveries, and this was a sufficient answer for the scoffers and doubters to give when questioned on the subject. Nevertheless, gradually it came to be seen that certain people would take hold of a farm of notoriously poor or bad character, and in the course of a few years would become comparatively wealthy, whereas previously, within the memory of man and within the legendary lore of the oldest inhabitant and Nestor of the village who had the history handed down to him for generations, every tenant on such and such farm in the parish had always either not benefited himself, or had been ruined out right. When therefore, a person on one of these farms was found to succeed, and it was seen that success followed the use of the new fangled manures, people began to see that there was something in it, and thus gradually success conquered ignorance and prejudice, and the sayings and recommendations of scientific men came to be over-appreciated. This naturally led to the advent of numbers of persons who, with either more or less scientific knowledge, established themselves as "Agricultural Chemists," analysed soils, charged high fees, and ended by recommending the newly discovered manures, which in the first place consisted of crushed bone or bone dust only.

Now, as the use of bone dust can never be mischievous on any land, and on land that really wants it works like a charm, these good gentlemen, who had recommended the article under such high fees, acquired great honour, and the faith of the farmers began to get unlimited in their advisers.

At first bone-dust quite coarsely ground was used, also, as it was called, "half-inch bone," that is to say, bones crushed into pieces about half an inch large in each direction; the bone dust was found to benefit the ground for at least three years, although there is little doubt that it did not yield up all its virtues even in that term. The inconvenience of manuring with one coat of manure which would last three years, was very soon discovered; if a tenant in the last year of his lease used the bone dust, he certainly got the benefit of a vastly increased crop, but he left an equal benefit in the ground for two following years, which he could not get paid for by the incoming tenant, and the consequence was a further reference to science to reduce the bone dust to such a state that the crop on which it was used might be expected to extract the chief benefit of it, without any large quantities remaining in the soil. Thus the use of capital would be saved, and the payment of two years' interest on the amount spent in this manner would be avoided. The result was the various preparations called "Superphosphates," in which the bones are dissolved in surphuric acid, and thus reduced to their elements, and the beneficial influences of the manure are brought into the immediate use of the crop, so that the crop following the use of superphosphate is supposed to extract the whole of the benefit. Various other methods of reducing the bones were resorted to, all with greater or less effect, but all intended for the one object, viz.: greater economy in the use of the manure.

The use of these various preparations of bone increased so fast in England and Scotland, and also in the best farming districts in some parts of the continent of Europe, that bones soon become scarce, and again science was resorted to. The next speciality as a foreign manure used was "guano," which is found by the deposits of the myriads of sea fowls and sea animals which frequent the islands in the Pacific, amongst which the most famous was from the "Island of Ichaboe," off the western coast of South America. There were various other islands in the same vicinity, and all these being situated in a latitude where rain is almost unknown, the deposits of guano were never leached by the action of water, or even heavy dews, and consequently not only retained all the usual insolnble elements of such substances, but all the soluble elements as well, particular ammonia, which existed throughout the substance in a very large proportion. In a considerable period the collecting and bringing this guano to England employed an immense number of ships, and the pursuit became a most important one. But the guano-bearing islands in the Pacific belonged to the Governments of Chili and Peru respectively, and these Governments exacted so high a price for it per ton, as to lead to the most exhaustive search all through the Pacific, Atlantic, and every other part of the tropical haunts of sea birds and animals, and fortunate was the captain and capitalist who discovered a guano island, belonging to nobody, where no export fees had to be paid. Such secrets were guarded with the utmost care, but of course could not long be concealed, and small wars were waged by private ships' companies, for the precious and coveted substance. Most of these deposits, enormous as they were, are now exhausted, or in a fair way to become exhausted, notwithstanding that in some of the islands the deposits were of hundreds of feet in thickness, and the substance was cut out of apparently solid cliffs, which towered one above the other to a considerable distance. The principal of these islands are now again abandoned to the birds and sea beasts, and the deposits are expected again to accumulate

Guano was found in analysis to consist of the phosphates with a small portion of sand, and the substances resulting from decay of animal matter, particularly ammonia: the birds who formed these deposits feed on fish and sea weeds, and the result was considered equal in phosphates, (from the bones of the fish consumed) to bone dust, and superior to it in ammonia.

As the Guano deposits began to fail in supply, science was again called in, and everything which would yield phosphoric acid to chemical tests was searched for, and when found, was converted to manurial uses. Mineral phosphate of lime, though entirely inert to vegetation, when used by itself, was found at once to yield up its treasures to the action of sulphuric acid, and consequently mineral phosphate, which is found in great abundance in certain rocks, was diligently sought for and converted to the use of the farm by scientific means. Coprolites also, another phosphate substance, was found in large quantities, and similarly reduced and passed into the use of the farmer.

Some of the largest deposits of mineral phosphate of lime which are known, are to be found in Canada, and that substance is now extensively mined, and exported to the all-devouring British Agriculturists, instead of converting and enriching our own fast failing fields. It is to be hoped, however, that this disgrace will soon pass away, and that Canadian phosphates will benefit Canadian lands.

After English farmers once allowed to themselves that science could help them, other substances as well as these already mentioned were sought for, and found, and are now in general use; but the further consideration of the subject must be deferred to a future occasion.

VECTIS.

Cow Manure.

The very best manure for all kinds of flowers, strawberries, and other small fruits, is cow manure. In fact, actual test has demonstrated that it is valuable as a manure for all kinds of vegetation, and better than anything else for the flower and small fruit garden. Cows feed upon herbage principally—the grasses, in their green or cured state—and the very essence of that herbage is applied to the plants in the shape of well fermented manure. I saved two cords of this valuable fertilizer last fall and winter in the following manner: I kept two cows, and a wheelbarrow and spade in my barn lot. I built two pens eight feet long, four feet high, and four feet wide, and covered them over with boards, leaving one end open. Knowing the value of this manure, and the difficulty of saving it properly if left lying about uncollected in the yard for the pigs and other stock to destroy, I told one of my boys that I wanted him to take it up with the spade and barrow every morning and evening, at milking time, and wheel it to the pens and throw it in. By way of encouraging him to do this work regularly, I agreed to give him twenty-five cents every Monday morning, as extra pay. He was faithful, and at the end of four months I had two cords of manure, worth more than the same quantity of any other fertilizer known, at a cost of only four dollars I would not have taken twenty dollars for it on the first of March. At that time I composted the two heaps with an equal quantity of sods from the roadside, wetting down the mass with soap suds, and on the first of April applied it to my flower borders and strawberry beds; and such flowers and fruit I never had before. Its good effects will be seen for years, or as long as I desire to keep the beds in cultivation with berries and flowers.—*Cor. Rural New Yorker.*

Frozen Roots.

In a former number of the Canada Farmer it was endeavoured to be shown that one of the best manurings which could be given to land for the purpose of renovating it, and preparing for a crop of wheat or barley, was a crop of roots destroyed on the land by the winter's frost, and then ploughed in as a cost of manure the following spring. Numerous instances were adduced in which such a course had been, both purposely and accidentally, followed, and with excellent and permanent results, and it was argued that if the whole transaction were carried through in the cheapest and best manner, that it would be an economical arrangement. Like everything new, it was received with incredulity, followed in many cases by unmitigated ridicule. People endeavoured to show that a crop of roots cost, in some cases, as high as forty dollars per acre, and although the more moderate calculators limited it to twenty dollars per acre, yet even at that rate it was declared that such a course would be extravagant and suicidal in the extreme; and it would not be too broad an assertion to make, that the recommendation has not been followed out in a single instance.

The present, or rather the late exceptional season, has taken the matter into its own hands, and the past fall and early winter have seen many hundreds of thousands of acres of roots throughout Canada, covered with snow in the fields, frozen up, and finally abandoned. This has been looked upon as a heavy visitation, but like most visitations, which at the time seem hard to bear, it may, and perhaps will, prove beneficial to the cause of agriculture, and show on a large scale either the falsity or the excellence of the views explained in the former article on the subject. If it should prove that such a manuring is the best that could be given, then every one's ideas will at once be turned to the cheapest plan of carrying it out in future.

The writer was, a few days since, in conversation with a most intelligent and well-doing farmer, and on asking the usual questions as to the progress of the crops, the farmer, with a heavy sigh, stated that he had been caught by the frost and snow, and that the largest portion of his root crop was now under the snow in the open fields, and, of course, destroyed. The matter was discussed, and the profits which the roots would have realized, by feeding to cattle, taken into account, and after all the farmer seemed to take the thing rather philosophically, observing, "If I lose on the cattle, I shall gain in the land, for it is the best thing that could be done to manure it, and I shall be sure of a big crop of barley, and if prices only hold, my loss will be more than made up, and my land will be all the better of it besides." Delighted at the expression of congenial views, the writer enquired what the farmer meant, and what crops of roots were left out. The farmer replied, a large piece of carrots, about two acres of mangolds, and a large lot of turnips. The carrots and the mangolds would, of course, be a dead loss, but he thought that some of the turnips might be fed in the spring. He was asked, had he ever known a crop of turnips or mangolds to be destroyed by frost in the ground, and then ploughed in. He replied, yes, that on one occasion, on his father's farm, near by where he lived, he had what was then supposed to be the misfortune to lose a crop of turnips in a similar manner, that the part so lost was only part of a field, the remainder of the roots having been buried in time. The result was, that although the land where the turnips were buried was worked and treated in the usual manner, and produced a good crop, yet the part where the turnips were destroyed in the ground had produced a far better crop; that the wheat was at least a foot higher on that portion, and you could tell to a line where the turnips had been destroyed and ploughed in, both by the excellence of the yield and the great increase in the produce of straw; and he added that the fact made so strong an impression on him that he should never forget it.

The writer then went into the subject with the farmer, discussed the merits of the plan and the cost, and finally received a promise of a full report of next season's operations, describing the improvement and otherwise of the succeeding crop, which was intended to be barley, and which results shall duly appear in good time in the columns of the Canada Farmer. The writer will feel obliged if others similarly circumstanced will report through the same channel the results of their experience.

VECTIS.

Stocking Pastures.

A subscriber at Richfield Springs, N. Y., asks, "Is it best to stock a pasture to its full capacity, or allow the grass to grow faster than stock can eat it down?" It will be found most profitable to stock as heavily as the land will bear, and the pasturage is sufficient to maintain in good growing condition. If the land is too lightly stocked, the animals will become dainty in their choice of food, and graze some portions closely while others are left almost untouched. The coarser grasses will then be seen growing up tall and rank in scattered patches, while clover and the finer and more succulent grasses will be cropped closely. This entails a great waste of food, as when some of the coarser grasses acquire a strong growth, and begin to run up to seed, they will not be eaten by any kind of stock. The best plan is to keep the pasturage at as even a growth as possible, by grazing different kinds of stock one after the other. Begin with the cows, let them have the first of it, and as soon as they have grazed it sufficiently, which will be as soon as their yield of milk shows the least falling off in quantity, put them on a better pasture, and let horses and young cattle follow, then sheep, and by the time the last have grazed it closely, if the land has not been overstocked, it will be late enough in the season to take all stock to their fall pasturage, and allow the summer grazed fields to be shut up in order that the grass may sufficiently recuperate before winter to give enough top to act as a mulch to the roots against severe freezing and thawing during late fall and early spring.

Where but one kind of stock is kept, dairy cows for instance, the better plan is to have the pasturage divided into three or four fields, and put them a week at a time, turn about, in each field in succession, beginning with the driest and earliest, so that the first pasturage will have sufficient time to grow thick and stocky before

the last one is fed off. This is particularly the case with clover, which is best not to be allowed to grow rank at any time, and especially when intended for pasturing milch cows.

Thin Sowing.

To the Editor.

Sir,—When in England recently I was much struck with the extent to which the theory and practice of thin sowing are extending. Mr. Mechi says that his "wheat from two pecks an acre is thick, and that raised from three and a half and four pecks an acre wants thinning." A Suffolk farmer, who has practised thin sowing some years, has decided, from different trials, that three pecks and five pints, or rather less, is ample seed for wheat. Wheat so sown does not go ahead as fast at first as that which is sown thicker; this is much in its favour, as it thus gets a better root-hold, whilst it is not being impoverished by tender shoots striving to outstrip their rivals in reaching the fresh air, so necessary to the plant. Thick sown crops seem to grow as if their existence depended on each plant out-growing its neighbour, thus expending their vitality to no beneficial purpose.

Thin sown wheat has strong, good straw, many heads to each seed sown, and good plump grain. The straw being stout and not too long, stands well in the field.

When it is considered that many sow seven, eight, nine, and even ten pecks of seed wheat per acre, the saving accomplished, alone, is a great object gained. If this quantity only is sown, the sample must be clean and good.

Barley, also, has shown good results from thin sowing. R.

Note by Ed.—Such thin seeding may do very well in Britain, where the soil is made rich and brought to a high state of tilth and the best drills are used, but would not be advisable in Canada, where climate and circumstances are so entirely different.

To Keep Birds from Seed Corn.

A good plan to keep crows and other birds from seed corn, and one of the efficacy of which we can speak from personal experience, is thus described in the *Country Gentleman*:

"The plan generally adopted by the farmers of this county, to prevent blackbirds from pulling up corn in the spring is: Put the corn, say one-half a bushel, in a tub or other convenient vessel, and pour over sufficient hot water to cover it; and let it stand a few minutes, or till the corn is thoroughly warmed; then drain off the water, and pour over the corn a very little gas or coal tar, which has been previously warmed till it is thin, and with a stick stir it thoroughly, which will give every grain a thin covering of the tar; lastly, dust over it some dry plaster or earth, to prevent the grains adhering together, and stir again.

Stock Department.

Breeding Horses.

In a former article on this subject we showed the folly of the too common practice of using mares as breeders without regard to age or fitness to produce healthy offspring. Having a mare that combines good form with perfect freedom from disease or defects of any kind, except perhaps those resulting from accident, and not attended with irritation, the next point to be attended to before commencing to breed from her is the selection of a sire.

Now one of the principal points to be looked to in a sire is purity of blood, from whatever source it is derived. There are but few fixed types of horses with the power to transmit those types to their offspring from common mares.

Those types are the thoroughbred racer, the Arab, the Suffolk, the Clydesdale and the Norman.

Of the first two we do not propose to speak, as the few we have of them are not the right kind, the tendency of the present racing customs being to breed animals of a leggy character, capable only of running a very short race at an unusually early age. Could we get a few sires of the thoroughbred class known in England as the old four-milers, and still found, to some extent, in Kentucky in the descendants of "Lexington" or "Scottish Chief," famous for their wind, courage and stoutness, and now chiefly used to breed weight-carrying hunters or extra good roadsters, much might be done to improve the quality of our travelling nags. For general farm work, combining strength, beauty of form, and colour, with docility and a quick pace in walking, the Suffolk is a most desirable horse.

The Clydesdale is perhaps the best known of any among us, and as a horse adapted to draw heavy loads over long distances at a slow pace, it stands unrivalled, but is too sluggish in temper and movements for farm work.

The pure Norman horse, an animal combining great strength and stoutness with moderate size and good action, has not yet been introduced here to our knowledge. The well known French Canadian horse partakes strongly of that type, having originated from a cross of Norman blood on the Indian ponies of the old settlers of Quebec.

One of the greatest evils of the present day among horses is want of character, resulting from the employment of animals as sires that have nothing to recommend them beyond their powers of trotting.

Now, it is an acknowledged fact among turfmen that there is no such thing as a breed of trotting horses. The Morgans and Black Hawks at best were but mongrels, having an infusion of the blood of the racer, and in no case has it yet been shown that a horse possessing trotting powers has been able to transmit his peculiarities in that respect to his offspring. There has never been any attempt made to fix the type of the trotting horse, nor can there be, for the gait itself is one that is acquired by diligent training, and as a rule, no trotting horse has shown any other quality that would be desirable to perpetuate.

A common mare may or may not produce a good colt by a trotting stallion, the result depending not on the trotting qualities of the sire, but on what blood he may have inherited from his ancestors. Stonehenge, the best authority on horses, says, "The pure blood stallion had no plebeian ancestors, and his colts, if not closely resembling himself, will still be good, inheriting the qualities of some ancestor, while the colts of a trotting stallion are likely to take after some dunghill grandmother."

Our earnest advice to farmers who desire to breed good horses is to employ only sires that are really of pure blood, and particularly to avoid using any of the class of trotting stallions now so numerous, and so persistently encouraged by the mistaken policy of many agricultural societies and judges of horse-flesh, in awarding their prizes on the credit of what they may have been trained to do, rather than for any good character or qualities likely to be inherited by their offspring.

Were every stallion shown at an exhibition required to produce a pedigree showing his descent from a known ancestor, as is now done with cattle, to entitle to a prize, there would soon be an end to all breeding from fancy mongrels, now getting too common for the good of the country. An old writer justly says:—"The worst scrub of a hack of pure blooded lineage will produce better colts from a cold-blooded mare than the handsomest mongrel that ever went on a shodden hoof can do."

The Prussian Government has just adopted an extensive scheme for improving the breed of horses of all classes, by encouraging the formation of local associations for the purpose.

The Prince Consort's Farms.

It was only on that cheerless Sunday, when the Prince Consort's name first passed from our litany, that England seemed to awake to a full and abiding knowledge of what she had lost. None had more reason to mourn him than the agriculturists. He had united himself more closely with them that very autumn by becoming the President of the Royal Agricultural Society, and taking the chair at the first council meeting in the session of 1861-2. Agriculture held a high place among the subjects to which that broad heart and piercing intellect had been applied. Those who knew him best said that you could not take a country ride with him and fail to see that his mind was ever at work, thinking out some useful problem on farm stock, land, or tree. In his six farms he took especial delight, and each new invention and mode of culture was tested there without fear or favour. He also determined that they should be the neutral ground, on which farm stock, whose merits are so magnified or depreciated by local prejudice, should have an impartial trial, as well as the head centre, to which the first agriculturists of all nations should freely resort and exchange minds on food for the million, and the labourers' welfare.

The history of the six farms, including those at Osborne and Balmoral, has been done so fully and so ably by Mr. Chalmers Morton, that it is beside our purpose to enter into descriptions of soils, farm buildings, and modes of cropping. We may simply say that the four farms in the "royal county" comprise 2,400 acres, of which 700 are arable.

Her Majesty has a private sitting-room adjoining Mr. Tait's (the manager's) house, round which are hung pictures of prize cattle, pigs, and horses, which have nearly all been bred on the Royal Farms. They are by Herr Keyl, a very skilful farm-yard artist; and, in fact, we have rarely seen a prettier composition of the kind than the white Smithfield heifer, with a robin sitting on the wire fence. There are from eighty to a hundred Short-horns in the biggin, and forty to fifty of them are in milk. The dairy produce is all required for the Castle and the farm; and when the Court is at Balmoral, 120 pounds of butter are forwarded weekly. A dozen Alderneys are also kept as cream stainers; and the great object has always been to retain the whole badger colour, as there is a better foreign sale for them. This, however, was found impossible of attainment as long as the Alderneys were tethered head to head with the Short-horns, and kept the roan and flecked colours perpetually in their eye. They are imported at an average of from 20 gs. to 25 gs., and increase considerably in size with the rich grass, besides growing rather lighter in their colour. No forcing can make them more than half fat, when their milking prime is over, and seldom more than £10 can be got for them at the butcher's. In the height of the grass one or two of them have yielded sixteen quarts per day.

Cold Cream and Alix, two Short-horn cows of the famous Earl of Dublin milking strain, which were purchased for 100 gs. each at the Fawsley sale, have given as much as from thirty to thirty-five quarts apiece at two milkings. These two cows have made the herd; but, instead of the usual system of "Bates upon Fawsley," bulls of the Booth blood, and direct from Warlaby, have been used. Prince Alfred, Fitzclarence, Lord Hopewell, British Prince, &c., were here in turn, up to the time of the sale in 1867, and since then England's Glory has been in residence. The cross hit very fairly. Cold Cream had ten calves—three bulls and seven heifers—and they and their produce have already made £1,651 10s., while those left may be very fairly valued at £450. The old cow never had twins, and the highest price for any of her descendants was Mr. McIntosh's 150 gs. for Duchess. Alix has survived her, and has just had her sixteenth calf in her sixteenth year. Two sets of twins have been her lot; and she has so far had eight heifers, but they have not sold for the same prices as Cold Cream's, and have only realized £721, with £600 still to the good. The biggin can accommodate sixty cows standing face to face. Its stalls are nine feet by six feet, and furnished with iron troughs, divided into three compartments for food and water; and a raised platform, flagged with asphalt, and formed with slabs of Penryn slate, runs down the centre of the building. Old Alix was there, still giving upwards of twenty quarts; but Cold Cream had gone to the butcher. Some purchases have been recently made from Mr. Fowler of the Prebendal Farms, Aylesbury, who has been very successful with the "Bates upon Fawsley" cross.

The foreign cattle which Her Majesty has received from Eastern kings and rajahs are tied up with the rest. Three zebus stand side by side; the bull, which is grey, being the smallest of the lot. His Platonic consorts are both white, and one of them has its horns erect, and the other lying back, almost flush with the forehead. They do not seem to have a trace of vice about them as they gaze at you with their mild eyes, and stretch out their chocolate noses to be patted. A Bramah bull, from Mysore, stands near them, and seems about the size of a very minute Shetland trick pony. He is most courteous in his solitude; and, at the words, "Salaam, Joe!" down he drops on his knees. His hump is said to be porous, like a tongue. In a time of great drought it will shrivel, and then swell again when the rains descend. We believe it is the same with the zebus. The Alderney bull is in the next box to the Swiss one, which puts the *Ranz des Vaches* and all its associations of happy vales and hills at a discount, with its pot-belly and its head like a bushel. A tawny lion-colored African, which looked like a fusion of West Highlander and Alderney, and was sent to Her Majesty, with two cows, by the King of Portugal, has died. The calves have nothing but skim milk after the first two or three days; and the loveliest little black-and-white nosed Alderney we ever saw had no exception made in its favour. There are no Ayrshires kept upon the farm.

About two hundred Cheviot draft ewes are purchased direct from the Sutherlandshire hills, which ensures a freedom from foot-rot. Half of them are crossed with Southdown and the rest with Leicester rams, and the lambs are sold from the teat to the Windsor butchers about June. At one time only Leicester rams were used, but as the taste for the "black foot" crept in among a mutton eating population, the Southdown was introduced, and, although they gain in quality, there is a reduction of about four pounds in the dead weight of the lambs. The ewes are bought by character at the great Inverness market, and come by sea to London. It is very seldom that more than one crop of lambs is taken from them, and then they come to hand very quickly for the butcher.

Black Norfolk turkeys, grey Dorkings, and Aylesbury ducks are all reared on the farm, and those which are not used at the Castle are sold to poulterers and fancy breeders. The hen-house is constructed on very useful principles. A fountain plays all day to furnish fresh water, and large heaps of sand are put down specially for rolling in.—*Mr. Dixon in Gentleman's Magazine.*

Breeding Sows.

Although thrifty well kept pigs will procreate at four to six months of age, yet it is bad policy to permit the sexes to come together before they are eight or nine months, so that the sows shall not be less than one year when they farrow with their first litter, the period of gestation being sixteen weeks or 112 days—old sows produce the largest, strongest and best pigs. Successively breeding from young sows for several generations lessens the size and probably weakens the vitality of the pigs. Sows that are good breeders can be profitably kept for four or five years—and if such exclusively are kept for breeding it will not be necessary to change the boar annually.

Sows kept for breeding should neither be starved nor made very fleshy, but should be fed with a view to the most perfect health and vigor; they should never be kept in a close pen, but should have sufficient range for exercise; easy access to water, with such a variety of food as their instincts call for. Deprived of food which they crave, they frequently destroy their young, the cravings of appetite overcoming the maternal instincts; when properly kept and fed, this never occurs.

As the time of farrowing approaches, more generous feeding is required. The increased demand upon the vitality of the sow must be met by a full diet; but it should be composed mostly of green, succulent, and light diet,

carefully avoiding all heating and stimulating food. Little or no dry corn should be given. House and dairy slop, bran, shorts and coarse provender, with a good pasture range in summer, and when that cannot be had, as in winter, some kind of both vegetable and animal food should be given.

A few days before farrowing, the sow should be put in a warm, dry, well sheltered pen, and protected from all annoyances.

Little or no food should be given the day after farrowing, and but light feed and plenty of water for several days. A pail of swill at this time will often prove fatal to the sow. Careful attention to these suggestions will seldom fail to secure "luck" in raising pigs, while a neglect of most or all of them will have a tendency to make such a farmer an "unlucky" breeder.

The best season for sows to farrow is April or May. The weather is then sufficiently warm, and the sows can get a taste of grass and insects, a very important consideration. The pigs have the entire summer for growth, which prepares them to meet the inclemency of winter without injury. An April or May pig is worth two August or three November pigs. The early pig can be fattened if desired the succeeding winter, and if kept till eighteen or twenty months, will attain the maximum weight of the race. The late pig must be kept through the first winter, and when fattened the succeeding fall, will weigh 50 to 100 lbs. less than the early pig, and his keeping will most likely have cost more.—*Prairie Farmer.*

THE WOOL GROWERS' AND SHEEP BREEDERS' ASSOCIATION OF THE COUNTY OF LENNOX.—Officers for the year 1870: President, Donald Fraser, Odessa; Vice Presidents, William Dawson, Selby; John Sharp, Bath; Secretary, Francis Van De Bogart, Napance; Treasurer, John Dunbar, Napanee. Directors, Nathan Caton, Garret Vanalstine, Nelson Dollar, Henry Huffman, S. K. Miller, C. W. Huffman, Shipman. Reuben

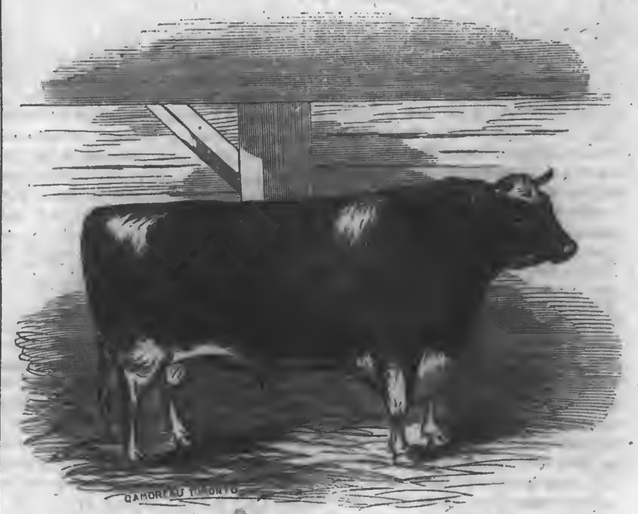
LIBERAL PREMIUM.—We direct special attention to the advertisement of the East Riding of Northumberland Agricultural Society, who, with commendable spirit and liberality, offer the handsome premium of $75 for the best stallion for general purposes exhibited at the Spring Show of entire horses, to be held at Castleton on the 20th of April. The competition is open to all without entrance fee.

CLYDESDALE HORSES.—When in Scarboro a few days since we had the pleasure of seeing two very fine young stallions of this breed, imported from Scotland by Mr. James Lawrie, of Malvern, in 1868. They are named respectively "Farmer's Fancy," and "Tinto." Their colour is bay, and they are very handsome animals, with good action and style. They are from a noted breeder in Scotland, and have very fine pedigrees. The dam of one of them has taken no less than seventy-four first prizes, and the dam of the other, four £50 prizes in one year, including that of the Highland Agricultural Society.

Holstein Cattle.

As the name indicates, this breed is of Danish origin, though now extensively spread over Holland and Belgium. It is believed that an early importation of these cattle to England formed the foundation from which the improved Shorthorns sprung, and their appearance indicates a strong resemblance to that breed, except in colour.

They have long been known and celebrated for their excellent milking qualities, and, no donbt, under the system of high farming and soiling carried out in Holland, have greatly improved in that respect of late years, the object being to breed them with a view to the development of their lacteal productiveness to the utmost.



They are of large size, with a very compact frame, have short horns and a fine silky coat of hair, and are invariably black and white in colour, being pied or mottled, but rarely, if ever, all of one colour. The cows in their shape resemble the Ayrshire, being largest at the hind quarters, and somewhat of that wedge form so characteristic of good milking stock.

As yet they are a new and comparatively untried breed in America, but one importation of them having yet come out. These were brought ont by a Mr. Winthrop W. Chenery, of Highland Stock Farm, Massachusetts, U. S. The weight of four imported cows, six years old, averaged 1,325 lbs. each—a heifer of two years 1,240 lbs. One of the cows gave, from 26th May to 27th July, two months, 4,018 lbs. 14 oz. of milk, or nearly 32 quarts per day. She continued in full milk up to the 24th of the following May, and the day after dropped twin heifer calves. This same cow, now 11 years old, is giving an average of 25 quarts of milk a day since February 10th, 1870, having calved January 18th. She gave 17 lbs. 14 oz. butter from six days' cream. Their milk is said to be exceedingly rich in casein as well as in butter, and they are likely to prove exceedingly valuable in cheese making districts.

Mr. Chenery has made two importations, but was unfortunate with the first, as they had no sooner arrived than that dread disease, the rinderpest, then alarmingly prevalent in Europe, broke out among them, and to prevent the disease from extending to the neighbouring herds, all except the bull had to be slaughtered. Even with the precautions taken, the disease spread to some of the neighbouring stock, but was finally stamped out by the energetic and uncompromising measures taken to stop the progress of the epidemic.

The bull Van Tromp, of which we give a portrait, was imported by Mr. Chenery along with the cows above noted, and his weight at five years old was 2,700 lbs.

The grade heifers got by this bull from native cows are said to inherit the good milking qualities of the Holstein blood to a very high degree. Their beef qualities

have not yet been tried, but their large size indicates that cows of that breed would be more profitable to turn to the butcher when past their best milking days than the Ayrshire or Alderney.

It is to be hoped that some of our stock breeders will try the experiment of introducing this valuable dairy stock, which, according to all accounts we have seen, are likely to be a much more valuable acquisition than the Jerseys, Alderneys, or, in fact, any breed excepting the Shorthorns.

Care of young Pigs in Winter.

It seems to be generally admitted that the stock of pigs in the United States is unusually light. At any rate, pork brings a very high price, and this fact, in the face of a tight money market, is pretty conclusive evidence that the supply is not equal to the demand It is not improbable that farmers will make, or have already made, an unusual effort to raise a large number of pigs next spring, and if we have a good corn crop next year, we may see a marked decline in the pork trade in the winter of 1870—1. But the indications now are that pork will be in demand through the coming summer, and early autumn, and we should make it a point to have our pigs in such high condition that we can avail ourselves of the high prices. Every farmer who has a litter of fall pigs should see to it that they are kept growing rapidly through the present winter, and during next spring and summer. A well-bred fall pig can easily and profitably be made to dress 250 to 300 lbs. at ten months old. But to accomplish this it is absolutely essential that the pigs be provided with comfortable quarters through the winter. and furnished with a liberal and regular supply of nutritious food. We do not advocate fattening pigs during our northern winter, but we do most earnestly advocate keeping young pigs growing vigorously. So far as our observation extends, half our farmers do little more than keep their young pigs alive during the winter. Whatever food the pigs eat is lost. They do not gain a pound, and they are so stunted that half the summer is past before they get into a thriving condition. No wonder such farmers say "pigs don't pay." Pigs kept warm, dry, and comfortable through the winter, with food enough to keep them nearly fat, will, when spring comes, grow with greater rapidity on food but little better than that which is ordinarily given to store pigs at that season; and so all through the summer, the effect of the good food and treatment in the winter will be very decided. With the run of good clover pasture, and the wash from the house and dairy, with a pint or so of corn a day, these well wintered pigs will gain rapidly, and will at any time be ready for the butcher. No matter what the price of pork may be, we are satisfied, from experience and observation, that if pigs are kept at all, the only profitable way is to keep them well. They may not always pay, but the liberal feeder has a better chance of getting his money back than the farmer who half starves his pigs.

Next to liberal feeding, a dry, warm pen is of the greatest importance. Better have a good pen, so constructed that neither wind, nor rain, nor snow can enter; but, in the absence of such a pen, the farmer is inexcusable who does not contrive some plan for keeping his pigs warm and comfortable. If made of boards, a few laths can be used as battens to stop up the cracks. We have seen pigs shivering in a pen close to a heap of stable litter, where half an hour's labour with a fork would have made the pen comfortable. No matter how the snow and wind are kept out. Anything that will stop up the cracks will answer. With litter or corn-stalks a rail pen may easily be made comfortable.

Cut Feed for Horses.

The various opinions that exist, relative to feeding horses to the best advantage, can only be decided by their owners making the necessary trial, and this will prove much more satisfactory than all the theoretical teaching on the subject that a man can read in a long day. The kind of horse to be kept, and the various sorts of work he may be called on to perform, will certainly cause a great variety in the results and verdicts pronounced. I have had as much experience with horses of all kinds, and of almost all descriptions of work, as any man can generally possess, and my opinion is decidedly in favour of cut hay and chopped feed. The hay must not, however, be less than from three-quarters to an inch in length as many records of inflammation of the bowls prove that horses of ravenous appetite may die from its use, if cut at a third to half an inch in length.

A horse comes in from work, say ploughing, at which he has been engaged since seven o'clock or probably earlier, until twelve or half-past at noon; a little water is generally given to quicken his appetite, and his feed is supplied. If half inch cut feed is used he will be found to grind only about one-half thoroughly, the other half being generally swallowed whole, and unchewed. If a hungry horse is then fed, and is at all subject to gripes, one day out of every ten he will probably have an attack of the malady, more or less violent, and it will not seldom end in inflammation of the bowels, and occasionally in death. This is caused by the irritation in the intestines of the unmasticated cut hay.

If cut feed of about one inch is used, the mastication will be much more complete, as the horse is compelled to eat more slowly, and the cause of itself is thus avoided. For many years I have tried this, and established the fact, beyond dispute, and my opinion was greatly strengthened by that of an old Yorkshire horse doctor, who had found, by nearly forty years' experience, these ill effects from cut feed (if half inch in length,) often occur.

With proper precautions and knowledge of how to use it; there is no doubt that cut feed is far the best and most economical, and amongst others, for these reasons:

1st. Horses so fed generally keep in better health, and as a natural consequence are much easier kept and are better up to their work, and less liable to ailments, especially *broken wind*

2nd. After feeding at evening—without hay in the rack to keep pulling at—the horse will generally lie down and rest, which the temptation of good hay before him constantly, will often induce him to neglect to do; and he will occasionally also rise during the night to eat—another temptation which is to a great extent avoided, if he is unaccustomed to find hay for his amusement.

3rd. You may feed cut hay and ground oats to any horse, young or old, no matter how warm, without danger of foundering.

4th. When cut feed is used, a very small quantity of water to damp the hay, (about half a pint is sufficient for each meal, before the ground grain is mixed with it), is absolutely necessary, or the hay will be rejected, and the grain be eaten, and by this alone a great benefit to the horses' wind is derived, immediate relief to a brokan winded horse being the consequence. If a very small quantity of salt is occasionally added to the water, it will tend to the general health of the animal. Do not, however, use too much, which is as bad as too little.

My experience goes to show that for particular work, damped cut hay, with ground oats, or other grain mixed with it, is far preferable and goes much farther than feed grain in the ordinary way; but the saving in hay is nothing in comparison, to the saving in time, and general health of the horse, and increased ability to do his work.

We all know that some horses will continue to eat good hay almost all day, and and if they are taken out to work, at a fast pace, with stomach distended by such poor food, almost certain injury is the consequence.

The fattening properties of so much hay may well be doubted, as few horses will

thrive on hay alone, even without work. I would much prefer cut wheat straw and grain (to the same value) to hay alone under almost all circumstances, especially for colts, and other horses will do more work at less cost when fed the same way.

C.

Feeding and Rearing Calves.

Many people, particularly in towns, so manage that their cows calve early in the spring before the grass grows. It is frequently found that a liberal feeding of hay and bran mashes scarcely supplies sufficient milk-producing food in order that enough may be obtained to rear the calf and to give a supply besides for the use of the family. I have found that the most nourishing food for the calf, when milk in large enough quantities cannot be had, or in cold weather when the "little stranger" requires plenty of food to keep up animal heat, is linseed meal, which proves an excellent substitute, and is in fact more fattening than the cow's milk itself. My plan of feeding is this: take the calf away from the cow so soon as it is born; if possible do not let it suck; feed it with milk from a common quart bottle at first; after a day or two it will learn to suck the finger and drink out of the pail. If there is not sufficient milk, boil a tea-cup full of linseed meal for half an hour in a quart of water, and stir it up with the milk. After the first two weeks the calf may be fed with half skim milk and the above quantity of boiled linseed, filling up the required quantity with water. Care should be taken to have the calves' mess as near as possible the same warmth that milk is when drawn from the cow. I have found that a calf will thrive and grow fat on this mixture.

Some people feed oat or corn meal, but there is danger of these "scouring," and thus losing the calf. Twenty-five cents' worth of linseed, or two and a half pounds per week, will be found quite sufficient, and this food will be found perfectly harmless. Calves should be kept in a warm, dry shed, with plenty of clean straw bedding, and properly and regularly fed. They can, with care and attention, be reared at any season of the year. I look upon it as a sin to kill heifer calves "Spare the innocents." P. G. B.

Ottawa, February 10th, 1870.

HEREFORD CATTLE.—Mr. Sandford Howard, the Secretary of the Michigan Board of Agriculture, who has paid considerable attention to the Hereford breed of cattle and written a valuable essay on the subject, says in a letter lately received: "I have strong faith in the profitableness of Hereford cattle where they are properly cared for, and are kept only for legitimate markets, without reference to speculation; and I do not doubt that the increase of the breed in Canada and the United States will be of public advantage. Indeed, I cannot but hope that the time is coming when Mr. Stone will receive the thanks of practical farmers, on both sides of the border, for his efforts in the introduction and propagation of some of the best specimens of this ancient and long-celebrated race."

Veterinary Department.

Diseases of the Horse's Foot.

NAVICULAR DISEASE.

The foot of the horse, from its complicated and highly sensitive structure, is liable to many diseases, and one of the most common, and at the same time most serious affections, is navicular disease, generally known as coffin-joint lameness. The parts involved in this disease are the navicular bone and its connections, and the extent of injury or abnormal change in the parts affected is found to vary according to the severity of the disease, and the time it has existed. Navicular disease, it is our opinion, may either be produced from injury to the tendon, or result from concussion and compression of the navicular bone. This is followed by congestion, or a sub-acute inflammatory action, which extends to the cartilages and synovial membrane, and in fact involves more or less the whole tissues in that region. The bone becomes ulcerated, and the cartilages destroyed. Plastic matter is also effused, which almost completely destroys the motion of the part. As a result of this severe and continued disease, the whole of the tissues entering into the formation of the foot become altered, leading to a contraction of both its sensitive and insensitive structures. Contraction at one time was erroneously supposed to be the cause of navicular disease, and other lamenesses to the foot, but the contracted condition of the foot is the result generally of internal disease, and particularly of navicular disease, or an effect of the foot not receiving its natural pressure from the ground. Although the term "coffin joint lameness" is frequently applied to this disease in Canada, the parts principally implicated are the navicular bone and the cartilage on its inferior surface, which forms what is called the navicular bars. This is for the purpose of allowing the tendon to play freely over the bone. The sub-acute inflammatory action attacking those parts may exist for a considerable time without greatly altering the structures, and in these cases the lameness is not severe, and disappears with exercise. After a time, the continued inflammatory action will produce ulceration of the bone, the cartilages and synovial membranes also becoming diseased. The tendon is also implicated in some cases, becoming thin and attenuated, whilst in others it adheres to the diseased bone produced by the plastic material exuded, or formed in the diseased parts. When the navicular bone or bursa presents these abnormal changes, permanent lameness is the result.

Like many other ailments to which horses are liable, hard work is often an exciting cause, as driving or riding horses rapidly when young, and not in a proper condition to undergo quick or violent exercise. It is also produced from injuries to the foot, or from cutting the sole too much when shoeing. It also results from a sprain to the tendon, or from allowing the shoes to remain too long without removing, the toe of the hoof in consequence becoming very long, throwing a greater strain upon the navicular bursa. Horses with short and straight pasterns are particularly liable to navicular disease when subjected to the tear and wear of streets and macadamized roads. In our next we shall notice the symptoms of navicular disease.

Staggers in Pigs.

To the Editor.

SIR,—On visiting my pig-pen a few days since I was surprised to find that two young pigs, aged about four months, which I had enclosed therein, were labouring under some disease of which I had not the most remote idea, and of which the following were the symptoms: They would walk about for a while in a state of evident stupefaction, and after a while would be seized with some spasmodic affection; they would then sit down on their hinder parts, and, elevating their heads in the air, would be seized with violent trembling, their under jaws quivering to a degree painful to behold. After labouring under these symptoms for a short time—from two to three minutes—they would again walk round in the state of stupefaction, and subsequently pass through the second ordeal.

Not knowing anything of the disease, I enquired of my neighbours if they had ever seen anything of the sort before. One told me the disease was called the "blind staggers," and recommended slitting their ears and cutting off a portion of their tails; this course was adopted. Another said the disease was called the "black tooth," and advised the punching out of all their black teeth; this course was also resorted to. Eventually, however, the sow appeared to be in a dying condition. I brought her into the house, and, as it appeared to me, she was affected with cramps; but before I could administer any remedy, she died.

I may say that the pigs have been kept up in the pen since November last. They have been well housed and taken care of, being fed on bran, house slops, etc. Perhaps you could inform me as to the name of the disease, and the best course to be adopted in such cases.

SUBSCRIBER.

REPLY.—The symptoms above mentioned were very likely the result of a disordered stomach, either from eating too much or from food containing some irritating or even poisonous ingredients. In similar cases we would recommend to give from three to four ounces of castor oil, and apply cold water or ice to the head. Cutting the ears and tail and knocking out of the teeth are practices too absurd to be tolerated in the present age.

WEAK KNEES.—A correspondent over the signature "South Dumfries" makes enquiry about a horse which is troubled with weak knees. "The only description," he says, I can give you of the trouble is that he shakes at the knees" Moderate work and plenty of nourishing food, together with good grooming and hand-rubbing of the legs, are the best remedies for weak knees.

BARREN HEIFERS—SWOLLEN UDDER.—A correspondent says he has "had three heifers at different times whose udders commenced to grow quite large when they were a little over one year old; they never got with calf. They would come in season generally every two weeks. The last of them I sent to bull in the fall. When I talked of sending her, one of my boys said, 'it is of no use sending her to bull, she will never get with calf.' 'Why so?' I asked. He replied, 'she has got a bag exactly like the others you had to beef on account of not getting with calf.' Now, it had never struck me that there was any connexion between the oases. However, it turned out just so. The heifer I speak of has been twice to bull, and has been in season again. Can you inform me whether those large-bagged heifers are apt to be barren, or can anything be done to cure them? The heifer is a very fine Durham grade, not too fat, but in good order.

REPLY.—In heifers that are highly fed the udder becomes enlarged, and sometimes also where there is a malformation of the generative organs.

TO PREVENT SOWS OVERLAYING THEIR PIGS—A railing or board should be fixed against the sides of the pen of a sow, before the pigs come, about eight inches above the floor, and it should jut out from the sides of the pen from eight to ten inches. When a sow lies down, if a pig or two happens to be under her, they will generally slide out and get crushed between the sow and the sides of the pen. If this railing is fixed around the nest, the sow's back, in lying down, will strike it, and the pig or pigs, sliding from under her, instead of getting crushed between the sow and the sides of the pen, will escape injury by sliding under the railing.

The American Farm Book mentions a horse that died at sixty-seven years of age, and another that was quite coltish in his forty-fifth year. These cases of longevity were doubtless the results of good care. It is never economy to put a horse to the utmost of his strength to obtain a great amount of work, or to feed sparingly to save provender.

The Dairy.

Canadian Dairymen's Association.

ANNUAL MEETING.

The Canadian Dairymen's Association held their third annual meeting, at Ingersoll, on Tuesday and Wednesday, February 2nd and 3rd. A brief session to organize was held in the morning of Tuesday, in the Town Hall, the President, Mr. Chadwick, in the chair, and Mr James Noxon being Secretary. The Chairman, at the request of the meeting, nominated the various committees, who were instructed to meet and report in the afternoon.

Business was resumed about two o'clock, and the committee reported the following order of proceedings:—

1st. The President's address.
2nd. Reports of Committees.
3rd. To what extent has the system of making cheese once a day been practised last year? Have card mills been generally used, and what have been the results?
4th. Proper treatment of acidity in cheese making.
5th. Rennet—Its nature and varied effect.

An adjournment from six to half-past seven, and for the evening session Mr. Willard's address.

The report was accepted, and Mr. Chadwick then delivered his address.

PRESIDENT'S ADDRESS.

The opening remarks of this very able and interesting address, of which only a brief summary can be given, referred to the improved condition and rapid progress of Canadian husbandry, and to the material prosperity of the country. Much of this improvement was due to organization, such as that by which the meeting was brought together, and to the consequent spread of information and stimulus to enterprise. The Association, though but in its infancy, had proved of very great advantage to the dairy interest; but it must not rest satisfied with its present position It should be the aim of all connected with it to extend and perfect its influence and efficiency The labours of the dairyman for the past year have been abundantly rewarded, a ready and satisfactory market for his products has been found, and a more than full average, both in yield and price, has been obtained, and the year closed with light stocks in both the productive and consumptive markets of the world. To maintain our success, it is necessary we should continue to furnish only the best article, and avail ourselves of all the aid to be derived from science and the practical experience of others. Provided Canadian dairymen can meet the tastes of their customers, the foreign demand for their products is likely to be permanent. The report of the Association for the last year, now published, was justly a source of much gratification, and gave good evidence of what had been accomplished. After referring to the interesting and instructive character of the American Convention which he had attended, and which strikingly showed what organization can effect, the President observed with respect to the Canadian trade, that the statistics of the cheese production for Canada were not to be accurately obtained, owing to the imperfect and irregular returns from the different factories "I have endeavoured to obtain as correct a statement as I possibly could of the amount shipped at the Ingersoll and Woodstock stations of the Great Western Railway, which amount I find to be—from Ingersoll, 2,237,687 lbs.; from Woodstock, 256 867 lbs. This is about 40,000 boxes, at a cost of $350 000. And of this sum $315,000 has been paid by two Ingersoll buyers alone. These few figures give some idea of the extent to which the business has been developed in a very few years, and it is, I think, destined to be very largely and very rapidly increased. Of the durability and still more complete development of the factory system there can be no doubt, and this fact is beginning to be generally acknowledged. The importance, in connection with this industry, of all the light of science is fully admitted, and the absolute necessity of a liberal education more than ever felt. It should be remembered that there are products quite as important to the farmer in this age as wheat, corn, cheese, choice animals or delicious fruitage; these are, elevating ideas and ennobling sentiments, products which can be grown through every month in the year, uninjured by cold or heat or rains or drought. Our ordinary business should be but secondary to the growth of the higher faculties. The man should be more important than his occupation, and not merged in it. This is an age that demands the highest improvement in every department. Society is moving upward and onward, and the farmer must move with it. Success in agriculture is not completed by adding barn to barn and field to field; however desirable this may be, yet I consider that he is an unsuccessful farmer who has not improved *himself* from year to year, constantly ministering to the comfort of the household, cultivating the heart as well as the soil, imbued with the idea that if we wish to see our country accomplish its highest destinies, we must have loftier objects of ambition than the mere attainment of wealth, at the same time appreciating the dignity of labour, also realising that labour becomes ennobled under the guidance of enlightened judgment, bringing in its turn a thousand blessings."

He congratulated the society on the re-engagement of Mr. Willard to deliver the annual address, and referred with pleasure to the satisfactory financial report of the year, urging all the members, in conclusion, to bestir themselves in promoting the extension and welfare of the Association.

After the reading of the address, the first question, in reference to *Making Cheese once a day*, came up for discussion.

Mr. YATES, of Belleville, said he was connected with a factory where the system had been adopted, and had been found to work well, saving labour, and producing cheese of a better quality and firmer texture. They used the milk of from 700 to 800 cows, divided over seven beats, the farthest point being about seven miles distant. In the evening the milk was put into the vats, to some of which ice in pails was applied, and in others Sterling Aiguire's Milk Agitator was employed. The Saturday evening's milk was in this way kept over till Monday, and had not been found deteriorated, except for a short time during the very hot weather. There was a slight difference in the cheese of Monday's make, but not enough to require any selection or culling in the sales. Preferred the Agitator to the ice, as it kept the cream from rising, which, if separated, could not again be properly incorporated. Cheese was considered better if made from a portion of old milk, provided it was sweet. Used 300 gallon vats, setting about 2,000 pounds of milk in each. The average yield of cheese had been 9 40 pounds to the 100 pounds of milk.

Mr HARRIS had also adopted the plan of making once a day, and employed the Agitator. He coincided with the previous speaker.

Mr. LOSEE, of Norwich, had tried the plan for two years with satisfactory results, producing a better yield, of better quality, with less labour. It was necessary to have the milk come in early, and in good condition, rejecting all that was not so. Had two vats of 500 gallons each, and used about 3,000 pounds of milk each day. The average yield of the past season had been a little under 10 pounds to the 100 pounds, and had sold at an average price of 12½ cents.

Mr BALLANTINE, of Stratford, had also tried the plan, but could not altogether endorse the views of the previous speakers He thought it was absolutely necessary to the production of fine flavoured cheese to get rid of the animal odour from the milk, for which purpose a certain amount of exposure to the air was essential—that mere reduction of temperature did not effect the object. He acknowledged that Mr. Losee's make on the once a day system was

of prime quality, which he attributed to his extreme care in manufacture, and the good condition in which his patrons had been educated to deliver the milk. In his own experience he had found the plan of making twice a day the better practice, and thought it impossible to make a first quality cheese from entirely new milk.

Curd Mills.—Mr. GRIFFIN said he had found benefit from their use in producing a better texture of cheese. There was, however, considerable difference in these machines, some of which scarcely altered the condition of the curd, and others tore it asunder too much, and thereby deprived it partially of its richness. The curd should rather be ground fine than torn asunder. In very hot weather he had used a temporary press, in which the curd had been subjected to slight pressure before adding the salt,—the curd mill being used twice, before and after the addition.

Mr. FAGEY said that he had used the curd mill during the past season, and found advantage from it. Sometimes, however, he had observed that cheese, so treated, lost a portion of its richness during the curing. This he attributed to some imperfection in the curd mill, for in other establishments, where a different kind of mill was in use, this difficulty had not been experienced.

Mr. FARRINGTON thought the discussion a very important one, particularly in reference to the first question, which had brought out some points of special interest. He did not think that the subject of the animal odour of milk had been definitely settled—some eminent physiologists contending that its presence was not an essential condition, while others maintained that it was present in all milk, without being derived from any extraneous causes. He thought the night's milk would have more of this odour than the morning's milk, and, for this reason, required time and exposure to get rid of it; while the morning's milk, being comparatively free, might be made up at once, and that hence the mixture of the two was not injurious to the flavour of the cheese. During the day, the cow was heated, perhaps excited and over-driven, and the milk was of too high a temperature, feverish and odorous; but, during the night, the cow being cool and quiet, the morning's milk was destitute of the animal taints. He thought it best, however, that in all cases there should be some interval between the time of receiving the milk and commencing operations in the vat. The plan of making once a day was universal in the States, and quite successful.

The question was laid on the table.

Acidity in cheese-making was the next subject brought forward for discussion. Mr. FARRINGTON explained that the cause of this acidity was the partial conversion of the sugar of milk into lactic acid. When this change had not commenced—when milk was used too new—the subsequent fermentation was apt to be too violent and to result in huffiness in the cheese. The proper degree of acidity was a matter to be learnt mainly by experience.

Mr. LOSEE said that the application to the curd of a hot iron, heated short of redness, gave a sure index of the right degree of acidity. When this was reached, the curd so treated could be drawn out by the iron in small sticky fibres.

The next topic for consideration was *Rennet*; and, as no one was prepared to open the discussion, Mr Farrington read an essay which had been delivered before the American Dairymen's Association, at Utica, on the same subject. The substance of this paper is given elsewhere, in the report of that convention.

Mr WELD, of London, diverged from the dairy business to pork-packing, and condemned the interference of Americans, who foisted in the market an inferior quality of swill-fed pork, which was calculated to damage the reputation of the Canadian articels.

Some one present asked if it was profitable, at the close of the season, to make cheese out of skim milk, rather than feed it to the swine.

Mr. BALLANTINE thought the profit depended upon the market, and that there was not at present any demand for skim milk cheese.

Mr. FARRINGTON was of opinion that at the end of the season—say after the 20th of November—it was best to adopt the American plan; skim part of the milk, and use only part whole milk, mixing the two together, from which to make the cheese. To make pork out of milk when cheese was fifteen cents a pound, was dear pork.

An animated discussion on this point ensued; some members concurring in the views of Mr. FARRINGTON whilst others, and Mr. CASWELL especially, most earnestly deprecated the practice of skimming the milk—a practice likely to be very much abused, and to deteriorate the quality of Canadian cheese. He contended that without skimming, even at the late season, cheese of the very best quality could be made by extra care; adducing in evidence of this statement the success of Mr. Sackrider, who had, so late as after the 15th of December, manufactured cheese of the finest quality, and that commanded the highest price. There was no practical difficulty in incorporating an additional quantity of cream in cheese-making, as was shown in the case of Stilton cheese.

The subject of *sour cheese* was brought up, and it was stated that cheese of this description need not be sold at a loss, inasmuch as if properly branded, and not smuggled in, there was a market for it in Liverpool, where cheese of this description was in limited demand for a certain class of consumers. It was necessary, however, that only a small proportion of this sour cheese—say four or five in a hundred—should be mixed with the better sort.

The benefit to be derived from cutting and cooking food was then briefly described. Mr. BAILLEY, of Norwich, spoke in favour of the practice, having found cut hay, scalded and steamed, much more nutritious than cut food given dry. A saving was effected in the grain required, as he had found two quarts of grain fed in this way keep the animals in as good condition as four quarts mixed with dry hay.

Mr. FARRINGTON adduced the instance of an American dairyman, Mr. Hopkins, of Herkimer county, who had proved the advantage of cooked food by a very conclusive experiment. He divided his cows into two lots of twenty each, and to one lot fed dry food, to the other cooked. In the latter case the flow of milk increased; while in the former it materially fell off. On reversing the trial, and giving the cooked food to the lot that had previously been fed on the dry, a corresponding change took place in the flow of milk, which again rose in the second lot fed with the cooked food, and fell in the other.

A brief discussion was brought up on the practicability of using windmills for pumping water for stock or dairy purposes. It was stated that these mills could be erected at a small cost, and had been found very serviceable in certain cases.

The meeting then adjourned until evening.

EVENING SESSION.

In the evening the convention met again at half-past seven. The hall was crowded to overflowing, and among the audience were a large number of ladies. In the absence of the President, from indisposition, the chair was occupied by the Vice President, Mr. George Hamilton, who introduced Mr. Willard to deliver the

ANNUAL ADDRESS.

This was a very able and instructive essay on milk and its products, of considerable length, occupying nearly two hours in the delivery, full of interest, and abounding in practical suggestions of great importance to dairymen and farmers generally. It is impossible in these columns to give the address entire, and any synopsis would fail to do it justice All that can be attempted is to give the leading points.

Mr. WILLARD commenced by expressing in very graceful and cordial terms the warm regard which he entertained for the Canadian branch of the great Anglo-Saxon family, and in this feeling he was satisfied he represented a large class of the most enlightened American citizens, whose minds were not warped by narrow sectional views, and who could rejoice in the prosperity of a sister nation so closely allied to them in blood and common interests—sentiments which were received by the audience with warm applause. He then entered on the special subject of the address by remarking that the natural home of the milk produce was a belt between the 40th and 45th parallel of latitude, stretching from the Atlantic to the Mississippi, and probably to the Pacific, comprising most of the Northern States and a large part of Canada. Of this belt only about a third is adapted to dairying. The dairy lands are quite irregular and not always contiguous. The best are characterized by high undulating surfaces, an abundance of never-failing springs and streams, a soil retentive of moisture and clothed with nutritious herbage of an enduring and hardy growth, a moderate temperature with an even rainfall, and a sufficient covering in the winter to protect the grass roots. Within this northern belt there is no description of farming that promises to be more profitable than the dairy, leaving out of the account such special cases as those situations which are peculiarly fitted for market gardening and fruit-growing near large cities. Compared with the chief branches of farming, dairying has the widest market and the least competition. It also gives peculiar opportunities for a mixed husbandry of the most remunerative kind, including that of raising the finest stock. The dairy farmer deals in three kinds of commercial product, milk, butter, and cheese, the last two highly concentrated articles of food of universal consumption and easy transport. In New York the question of comparative profit has been closely studied for years, and they have learnt that it is useless to compete with the West in grain, or with Texas and other sections in wool or in cattle; whereas, the demand for dairy produce has steadily increased, and the price has fluctuated less than that of other products. The annual yield of the dairy and grazing land is also more uniform than other branches of farming, and the nature of the husbandry rather enriching than exhausting to the soil.

The great question of dairy farming, especially since the introduction of the factory system, has been the possibility of over-production. But experience and statistics, thus far, have shown that both in Europe and on this continent production does not even keep pace with the demand. In the article of butter especially, though there has been a large increase, there is a great deficiency in the production. Everywhere in cities you hear loud complaints of the difficulty of procuring good butter, and the monstrous price at which it is sold. This deficiency is attributed by some to the operation of cheese factories, but is rather to be accounted for by the increase of population and the gormandising habits of the people in the use of butter. There are no such butter eaters in the world as the Americans. Everything that they cook must be swimming in butter. Irish domestics who never ate a pound of butter during their whole lives before reaching these shores, seem never able to get enough of this unctuous food Indeed, the waste of butter on this side of the Atlantic is frightful; and certainly the dairyman's prospects in this direction cannot be said to be at all discouraging.

In the article of cheese, also, there is a greatly increased demand for home use. The production of American cheese has advanced from 103 millions of pounds in 1860 to 270 millions of pounds in 1869, and yet the amount exported is but little increased. In addition to the growing use of cheese at home, the distant market has been largely extended by new railroads, and it is possible that the cheese factories of the country will be taxed to their highest capacity to supply the demand.

In the remaining branch of the dairy business there is also a rapidly increasing consumption, and it becomes a matter of no small difficulty to supply the cities with fresh milk. The real question for the dairymen should be so to equalize the supply of the three products—milk, butter, and cheese—that the highest price may be obtained for each. The difficulty to be guarded against is not so much the

over-doing the dairy business as disturbing its equilibrium

The difficulty of providing an adequate supply of fresh milk has led to the introduction of a process for condensing milk. An establishment for this purpose has been in operation for some time in Elgin, Ill. City consumers who use this condensed milk prefer it to fresh milk as it is usually sold, and find it both cheaper, and every way more convenient for use. The condensing process consists in evaporating the milk at a temperature short of 212°, until it has lost 75 per cent. of its watery constituents. It is thus reduced to a thick fluid of the consistency of syrup, and is then put up in hermetically sealed cans. The greatest attention is paid in the first place to having the milk pure and in perfect order, and in the process of condensing, it is repeatedly strained In some cases sugar is added during the operation; but this is not essential. This milk is sold at a price equivalent to fourteen and a half cents per quart of fresh milk, and as the cost of the process cannot exceed four cents, this brings the value of the milk to ten cents a quart.

Another branch of the dairy business that has been found very profitable in New York is the creamery, or butter factory. In these establishments the milk that is delivered by the farmers is partly sold as fresh milk or cream, and partly made into butter or "skim cheese." It has been found that fourteen quarts of milk will make, on an average, one pound of butter and two pounds of skim cheese The milk is not robbed of all its cream, and the cheese is sold at a price but little below that of whole milk cheese; while the butter is of the very best quality.

The speaker then adverted to the extreme importance of farmers being trained to keep correct accounts, so as to sell in accordance with the cost of production; and he deplored the lamentable defect of this principle of sound business economy among the great majority of farmers.

In reviewing the operations of the past year, three great lessons were taught.

1st. That a low, even temperature, and a comparative humid atmosphere in July and August are of service in preserving cheese in flavour, and hence that more attention must be given to the construction of curing rooms, so as to meet the conditions of our hot dry weather.

2nd. That a healthy consumptive demand for cheese does not depend upon extreme low prices.

3rd. That there are markets and an outlet for our whole product at a price above cost.

The opening up of new railroads has dissipated all fear of over-production, and as new territories thus reached become peopled, the American dairyman will soon cease to export, and may even be compelled to purchase from Canada as their nearest market. Good cheese, of the finest quality, Mr. Willard contended, should be worth eighteen cents. Of the poor grades it did not much matter what was the price, and the makers of such needed the sharp lesson of loss to compel the adoption of a better practice. There is no profit in producing a poor article.

Mr. Willard next referred to a new economy introduced into the dairy system, namely, the manufacture of whey butter—that is, butter from the whey after making cheese. As much as twenty pounds of butter can be made out of 500 gallons of whey, and the quality of the butter, if properly made, is such that it can with difficulty be distinguished from the best cream made article. Moreover, after the process the whey is just as nutritious food for hogs as if the butter had not been extracted. Hence there is a great waste in omitting the manufacture of this article from the cheese factory system.

Adverting to the profits of dairy farming in Herkimer county, the speaker mentioned the great loss which had resulted from the prevalence of abortion among cows, and suggested that it might become advisable as a remedy for this evil to adopt the plan of spaying the cows—an operation comparatively free from danger, and which offered many advantages, especially to dairies for the supply of city milk. It is affirmed as the result of experiments that a cow thus operated upon in her sixth year, and about forty days after calving, will continue to give the same flow of milk as long as her owner chooses to keep her.

The next topic touched upon was the necessity of a better concentration of forces and more thorough work—the determination to do at least one thing well instead of so many things superficially. This was especially necessary in the dairy business, in which a good article always realized a profit, while a poor one might be sold below cost It costs no more to make a pound of butter that will sell readily for fifty cents, than a pound of grease that goes begging at ten cents. The requisites for producing a good article of butter were the following;

1st. Securing rich, clean, healthy milk, obtained, if possible, on rich old pastures free of weeds.

2nd. Setting the milk in an untainted, well ventilated atmosphere, and keeping it at one even temperature—from 55° to 60°.

3rd. Proper management in churning.

4th. Thoroughly expelling the buttermilk, and working so as not to injure the grain.

5th. An even incorporation of pure salt, and packing in oaken tubs, tight, clean and well made, and storing in a perfectly sweet cellar.

Cleanliness in all the operations is an imperative necessity.

The best plan for securing an even temperature is to set the milk in vessels plunged in cold spring water; but in the absence of this convenience, a good method is the use of the Jennings' pan, which is a double receptacle, the inner one of tin for the milk, and the outer one of wood, with a space between for cold water.

Some details were given of the manufacture of Philadelphia butter, in reference especially to samples which were shown as the recent Dairymen's Convention in Utica. In the preparation of this choice article, the chief points attended to were, 1st. The food of the cows; 2nd. The temperature; 3rd. Neatness and dainty refinement at every step, from the moment the milk flows from the udder till the dollar in currency is paid for the pound of butter. In regard to the food of the cows, nothing had been found superior to clover or early mown hay. Indian meal was considered an important adjunct. Roots, with the exception of carrots, were not used. The temperature of the milk and of the churning old not vary much from 58°. In the after manipulation the butter was handled as little as possible The purest salt is used in the proportion of an ounce to the pound. The mass is made up in pound balls, neatly printed, wrapped in a linen cloth, and sent to market in cedar boxes lined with tin.

The subject of curing cheese was next considered In this process an even temperature of about 70° was the great desideratum; and the maintenance of such a temperature in the curing room during the hot summer months is the chief problem for practical men to solve. The past exceptional season had, from its low temperature, been peculiarly favourable, and had no doubt contributed much to the improved quality of the cheese of 1869. The proper temperature favours the breaking down of the tough curd, or casein, into the mellow, rich substance of the best cheese. Properly cured in this way, the cheese may be none the worse for the abstraction of part of its cream.

The speaker referred again to the importance of a home market for cheese, and the advantage of encouraging a home consumption of the article. One means of doing this was the manufacture of smaller cheeses—such as could be sold whole for $2 or under.

Some observations were made on the cheese production of Great Britain, the amount of which varied but little, and Canadian Dairymen were warned against putting faith in unfounded reports of any large increase of the cheese crop of that country—reports set forth to induce a lower price for the Canadian article.

The address concluded with an appeal to farmers to see that they faithfully performed their first and essential part in this important industry, by providing clean, healthy milk for the production of good cheese and butter. There must be scrupulous cleanliness, and gentleness in the treatment of the animals. All nervous agitation is highly injurious to the quality of milk. In laying out farms, reserve the uplands for pasture and the lower lands for meadows. Use variety of grasses in pastures. Provide corn fodder at the rate of an acre for every eight cows, so that when pastures begin to fail in July and August, there may be an abundant store of succulent food at command to keep up the flow of milk, and in this way both land and stock will be turned to profitable account.

At the close of the address, the speaker was warmly applauded, and a vote of thanks was proposed by E. C. Bodwell, Esq., M. P. P., who justly eulogised the instructive character and literary merit of the address, cordially reciprocated on behalf of Canadians the fraternal feelings to which Mr. Willard, as the representative of his countrymen, had given utterance, and trusted that friendly relations would continue, and be yet more closely cemented, alluding in passing to the importance of liberal commercial arrangements on both sides

The resolution was briefly seconded by Mr. Weld, and enthusiastically responded to by the audience rising and cheering heartily.

A vote of thanks to the ladies for their presence and encouragement was then passed, and the meeting adjourned till ten o'clock on the following morning.

SECOND DAY'S PROCEEDINGS.

MORNING SESSION.

On Thursday morning the Convention met again, and Mr. Chadwick opened the proceedings by calling for the Second Report of the Committee on order of Business. This was presented as follows:

1. Report of Committees. 2. Election of Officers. 3. Place of meeting. 4 What has been the general reputation of our cheese in the English market, and what are the defects to be overcome to bring it nearer the standard of the best English cheese? 5. Hoof disease. Has it prevailed among dairy herds, to what extent, and the best mode of treatment. 6. The best variety of corn for soiling, and where pure seed can be obtained. Adjournment from twelve to one. Financial report, and any other subject relating to the dairy or dairy farming.

This report was accepted, and the Committee on Nomination of Officers presented their report, naming for President, James Noxon, of Ingersoll; for Vice-President, W. S. Yates, of Hastings; 2nd Vice-President, Thomas Ballantine, of Perth; Secretary-Treasurer, E. A. James, of Ingersoll.

This report was also received, and the officers declared duly elected.

The next business in order being the choice of a place of meeting in 1871, it was moved by Mr. HAMILTON, seconded by Mr. BALLANTINE, that Ingersoll be the place appointed.

Mr. DALY, of Belleville, moved in amendment that Belleville be chosen. In support of his motion, Mr. Daly submitted that Belleville was situated in the midst of a good dairy district, where the factory system had been for some time in operation; that it was desirable to extend the benefits of this association and the influence of these conventions to other centres, and that the interests of the Association itself would be thereby promoted. He would only ask for the meeting to be held there one year, and would guarantee the hearty co-operation and friendly offices of the people in his neighbourhood to their visitors on the occasion, as well as an increase in the number of members from that district, and was perfectly willing that after next year the place of meeting should, if it were thought best, be permanently fixed at Ingersoll.

The amendment was seconded by Mr WELD, and supported by Mr. FARRINGTON, who, while conceding to Ingersoll the undoubted prior claim, and he might

ny the right, to the appointment, contended that considerations of the general interest favoured the removal of the Convention for at least one year to some other point. The Association professed to be Provincial, but was in fact local.

Mr. CASWELL enquired what had been the practice in New York State.

Mr. WILLARD replied that with the exception of the first year the meetings had always been held at Utica, though several efforts had been made to move it to other places. Utica was selected chiefly as being most central.

Mr. NIXON thought that the slight attendance at Roseneil of members from Hastings did not give evidence of a very warm or extended appreciation of the privileges sought, and that they had no guarantee, even by a constitutional rule, which was itself subject to change, that if the meeting were once held at Belleville, it might not be voted there permanently by an overwhelming local majority, for it must be remembered that they had to deal with ordinary human nature, in which self-interest was ever paramount.

The amendment was put and lost. The original motion was then submitted, and carried by a very large majority.

The Quality of Canadian Cheese being the subject first in order, the Chairman called on Mr. CASWELL to open the discussion. He stated that during the past season the quality had been, on the whole, better by far than that of last year, owing in part, no doubt, to the season, but not entirely so, for the improvement had been specially marked in certain factories, whilst others had deteriorated. He had shipped very extensively, had been extremely careful in inspecting and testing every lot, branding each, according to its true quality; and he had invariably observed that where a defect had been noted on this side, a corresponding depreciation in the price had resulted on the other. He had taken pains in many instances to trace the cause of the defect, and had found it attributable in some cases to want of cleanliness in the milk cans, in others to some fault in curing, to the use of bad rennets, and to a loss of cream. The most frequent complaint against certain cheeses was that they were "short of meat." In consequence of these differences of quality, the prices he had received had varied from $1 to $7 per cwt. in the same shipment. The first desideratum for cheese in the English market was quality, the next flavour. The best means to secure the finest quality were, in his opinion, besides scrupulous cleanliness throughout, the nicest care, an even temperature, and good ventilation in the curing-room—no factorymen should ever allow their cheese to be shipped before it was perfectly cured, and most emphatically no skimming should be permitted.

Mr. FARRINGTON observed that defect in cheese was often attributed to skimming where none of the cream had been removed, the faulty condition being due to some other cause. June cheese, for instance, was apt to be tough and to possess the appearance of skim cheese. The proper remedy in this case was to employ a lower temperature, and to continue the process longer. Some enquiry having been made on the effects of using the curd of the stomach with the rennet, Mr. Farrington had found no benefit whatever to result from the practice; but, on the contrary, it was apt to impart a sour flavour to the cheese.

Mr. DALY called attention to the importance of a prompt delivery of the cheese at its destination, and cited instances where cheese had been detained in the vessel after its arrival at Liverpool for several days, had heated in consequence and suffered damage. He was pleased to be able to state that notwithstanding all these difficulties, he had found during a recent visit to England that the reputation of Canadian cheese was greatly raised, and he had seen samples of our manufacture in Liverpool that were considered equal to the finest fancy brands.

At this stage of the proceedings the meeting adjourned till one o'clock.

AFTERNOON SESSION.

Corn for Soiling was the first subject taken up, though not first in order. Mr. GALWAY had used it and found it advantageous as green food when pastures were short, and when it was cured and fed dry it was more nutritious and productive of milk than the best hay. His method of growing it was to plant on sod ground, ploughed and harrowed, in drills sixteen inches apart, using two bushels or two and a half for seed per acre.

Mr. BAILEY also testified to the value of this fodder, but his mode of culture was somewhat different. He chose rich ground, setting the rows as much as three feet apart, using three bushels of seed to the acre, and cultivating assiduously.

Mr. A. GARNER, of Drummondville, had found the best results from sowing the corn broadcast.

Mr. JAMES would not sow far apart, preferred sod land, was careful to put in the seed early, by about the 28th of May, and, if possible, not later than the 2nd of June. Had cut the crop last year with a reaping machine the process by hand being tedious and expensive; had harvested with the reaper about four acres a day; preferred to cut while the plant was yet green and juicy, about the 1st of September. After cutting, left it for three or four days on the ground, then gathered it and piled it in shocks or stooks in the usual way, hauling it away by a team and chain during the winter as it was wanted. By this feed he estimated more cows could be raised on the same land, one acre of corn being equal to five acres of meadow, and not more exhausting to the soil than grass. The Western corn was the variety best adapted for the purpose. It was to be procured from the Western States, and he recommended the purchase of selected seed corn.

A paper on pastures was received from Mr. MACKELCAN, of the CANADA FARMER, and reserved for publication in the official report of the Association.

Hoof Disease.—A paper on this subject was read by Mr. HARRIS. The disease affects only the hind feet, is attended with inflammation, suppuration, and sometimes results in the loss of the hoof, and prevails most in the winter. The treatment he recommended was making a couple of incisions on each side of the leg above the hoof, and inserting into the cut red precipitate and garlic.

Some desultory discussion ensued, and it was evident that there was not a sufficient discrimination in the nature of the disease, which was by many confounded with foot-and-mouth disease, or with the effects of inflammation and gangrene from frost.

Mr. WILLARD said that the method of treatment adopted in Herkimer County was either corrosive sublimate applied to the sores, to promote suppuration, or red precipitate applied to the surface without any cutting of the skin.

FINANCIAL STATEMENT, ETC.

The Finance Committee gave in their financial statement, which showed the receipts for the year to be $306 49
The expenditure..... 268 86

Leaving a balance in hand of..... ..... $ 37 63

A vote of thanks was given to the Executive Committee for the very efficient manner in which they had discharged their duties during the past year.

The question of the best breed of cattle for the dairy was slightly discussed, Mr. James giving the preference to grade Durhams, and Mr. Farrington, looking more at the milking quality than the breed, preferred, on the whole, cows of comparatively small size.

On the subject of salt it was generally conceded that the quality of the Goderich salt would be superior to any if it were only drier. In consequence of the defect of moisture, preference was given by some to the best Onondaga or the Liverpool dairy salt.

After a vote of thanks to the retiring President, the Convention adjourned about four o'clock.

American Dairymen's Convention.

In consequence of our failing to receive, in due course, an exchange copy of the *Utica Herald*, containing a full report of the Dairymen's Convention held in Utica, we have not been able to give an earlier notice of this important and interesting meeting. From a supplementary copy of the *Herald*, kindly furnished by the publisher, we condense the following record of proceedings, and regret that our limited space precludes a more detailed account, for the meeting appears to have been of the most interesting and instructive character.

The convention met on the 12th of January, and, in the absence of the President, Hon. H. Seymour, the Vice-President, Hon. F. G. Alvord, occupied the chair, and opened the meeting with an appropriate address. The morning session was then occupied with the usual preliminary business of appointing committees, &c. In the afternoon, some reports of committees having been received, and among them one upon the subject of the tax on the sale of cheese, it was resolved to petition the Legislature for the repeal of the same.

Professor James Law, of Cornell University, then delivered an address on "The feeding of cattle in relation to their health and produce."

It was, he said, a matter of sincere congratulation that two of the maladies most dreaded by the stock owners of the old world—rinderpest and epizootic aphthæ—were happily unknown on the American continent. The Texan fever, now that the mode of its propagation is known, need never again find its way north of the thirty-fifth parallel of latitude. Pleuro-pneumonia alone threatens our doors, but as the cattle trade is almost exclusively from West to East, the disease will continue to hover around our Eastern homesteads wherein circumstances are favourable.

"If the cattle trade went from East to West, not only Western New York, but the vast States of the East must be devastated. The sound policy for the American agriculturist to pursue in regard to this disease is to make a vigorous and sustained effort to annihilate it, until the last affected beast has perished. He referred to the various constituents of food, and the importance of giving such as would supply the animal with the requisite material for repairing the waste continually going on in the body, and for maintaining health. Cows which are yielding milk and are pregnant experience a large demand for tissue-forming elements, that neither their own system nor that of their progeny may suffer in nutrition or development.

A certain amount of liquid in intimate connection with the proximate principles will serve to facilitate their assimilation, and thereby increase their value. As an example of this, he said a bullock may be kept in fair condition on one hundred and twenty pounds of turnips daily, but could not be supported on eight or nine pounds of hay, though as

judged by their relative amounts of proximate principle, their nutritive value should be nearly the same. The plentiful supply of liquid to the blood and tissues not only favours the destructive and reparatory changes in those, but maintains in full activity the various secreting organs. To combine the requisite objects, roots were especially adapted as food for dairy cows, and when their value was better appreciated would, no doubt, come to be extensively grown on this continent, as they had long been in England and Europe generally. In conjunction with these, corn or pea meal should be given in due proportion. The advantage of cooking food, and giving it slightly warm, was referred to, as well as the importance of variety in the diet. A brief but comprehensive review of the various diseases arising from errors in feeding concluded the very able address.

Mr. Willard next spoke on the profits of dairying. He dwelt on the necessity of every farmer keeping an exact account of profit and loss, so as to be able to regulate outlay and prices.

Reference was made to the profits of other branches of the dairy besides cheese-making, and statistics given to show that at present butter is a far larger and more valuable production than cheese; for while the cheese made last year amounted to about thirty-six millions of dollars, the butter during the same period reached nearly two hundred and ten millions. "The butter dairymen," said Mr. Willard, "have been very quiet. They have organized no societies, but have pocketed their profits without a word of complaint." Certain buttermen make 240 pounds of butter from each cow, for which they receive one dollar per pound the year round. This gives a profit of $240 per cow, to say nothing of the skimmed milk. With regard to the production and consumption of cheese, it was stated that last year's produce was 230,000 000 pounds, nearly two-thirds of which were absorbed by the home market. The consumption of cheese on this continent has very much advanced, in consequence of the increased population, the opening up of new railroads and the improved quality of the article. He recommended the manufacture of small cheeses for home use, as they would be more convenient to retail dealers and consumers. Upon home consumption the dairymen must chiefly depend for the maintenance of remunerative prices, which should be regulated by the dairymen themselves, on the basis of the cost of production, and not by the dealers and shippers, whose object, of course, is to lower the price at which they buy from the former. It was for this reason that co-operation among dairymen was so important.

The speaker next referred to a branch of dairy industry which has recently been found especially profitable—the production, namely, of condensed milk, which had been very successfully carried on in Elgin, Illinois; and estimated that the milk so disposed of realized a profit of ten cents a quart.

The practice of spaying cows was briefly adverted to—an operation said to be neither dangerous nor difficult, and to secure the following advantages: 1st. An increase of one-third in the quantity of milk. 2nd. A uniform quantity. 3rd. Freedom from accidents to which the cow is liable during periods of heat. 4th. Immunity from the accidents of gestation and calving. 5th. Greater disposition to fatten when the animal is dry. Mr. Willard, in conclusion, strongly urged the necessity of organization and concerted action among farmers.

The committee on prize essays next delivered their report, and announced the award for the best essay on cheese as an article of food in favour of Mr L. B. Arnold, of Ithaca. The successful essay was read at a subsequent stage of the convention.

The election of officers was the next business taken up, and resulted in the appointment of the following officers for the current year:—President, Horatio Seymour, of New York. Vice Presidents, Hon. T. G. Alvord, New York; Anson Bartlett, Ohio; X. A. Willard, New York; Sandford Howard, Michigan; Henry Wade, Canada West; O. S. Bliss, Vermont; Moses Hawks, Illinois; Asahel Burnham, New York; —— Bartholomew, Massachusetts; G. H. Kliphart, Ohio; T. S. Harison, New York; N. W. Woodfine, North Carolina; C. H. Wilder, Wisconsin; John M. Webb, New York; S. M. Wells, Connecticut; H. Calmes, Kentucky; Levi Wells, Pennsylvania. Secretary, G. B. Weeks, Syracuse, New York. Treasurer, Dr. L. L. Wight, of Whitesboro, New York. The names of G. B. Moss, of Greene County, and C. B. Chadwick, of Canada, were subsequently added to the list of Vice Presidents.

Mr. Arnold, of Ithaca, next read a paper on rennet, its nature and use. The subject was treated in a very comprehensive and practical manner, and no adequate idea can be given of the merits of the essay by such brief notice as can be given in this place. It was shown that the old idea of the active principle in rennet being an acid must be abandoned, as disproved by many experiments, and that its action was rather due to the presence and development of organic matter, composed of an almost infinite number of extremely minute cells. These organic particles retained their vitality, so to speak, under a great variety of conditions, but were destroyed by a high temperature, though how much below 212° did not seem to be exactly determined. These infinitesimal bodies, though insignificant, comparatively, when acting alone, work out most important results in their aggregate, and are the cause, not only of the coagulation of milk into curd, but of the subsequent change of the curd into cheese.

The structural nature of the active agent in rennet renders it susceptible of separation from the disagreeable odours that usually accompany it. To accomplish this has long been a desideratum among dairymen. It may be done by filtering rennet through charcoal. If the coal is finely pulverized, and thoroughly saturated with water so as to prevent the cells from lodging in its cavities, they will nearly all pass through with the fluid that contained them, while the odours will all be taken up by the absorbent power of the coal. A filter for this purpose may be made by perforating the bottom of a butter tub, or anything similar, and laying several thicknesses of muslin on the bottom to catch the coal dust; then lay on two or three inches of pulverized coal and on it one thickness of muslin; then lay on clean sand enough to hold the coal in its place. The sand will assist also in distributing the rennet over the whole surface of the coal. Then pass water through the filter till it will run through clear. The liquid rennet may then be passed slowly through by falling upon the sand in a stream proportioned to the size of the filter, when it will come through sweet and pure, with its efficiency but little abated. Rennet thus deodorized loses all tendency to huffing, and also its ability to give any bad flavour or smell to the cheese.

There is another method of deodorizing rennet that is more convenient, but not quite as perfect as the one just described. It consists simply in putting a small quantity of carbolic acid in the water, or whatever liquid the rennets are soaked in. Carbolic acid is a very powerful disinfectant, and a small quantity will neutralize the odours in a batch of rennet. Ten drops to a gallon of water are sufficient. It does not act instantly. It unites with the water slowly, and is slow in deodorizing the rennet. It should be put in at the time of putting them to soak, and by occasionally stirring it will have accomplished its work by the time the rennet is ready for use. If too much acid is used, the rennet skins will be dissolved, and animal matter be carried into the cheese, producing effects worse than if the acid had not been used. The difficulty of obtaining the acid pure is an objection to its use. Carbolic acid is also a powerful antiseptic, and may be used in the place of salt in preserving rennet skins. Under the most favourable circumstances, the use of salt in preserving green rennets occasions considerable loss. If salted and hung up to dry, the best part is lost by dripping, and if packed in brine, so much of the animal odour is retained in the brine as to make its use objectionable. In the use of carbolic acid these effects are avoided. Ten drops of acid are dropped into a bowl of water large enough to cover the green rennet when laid in it, say one pint. The stomach, when taken from the calf, is turned inside out, and carefully cleaned and laid into the acidulated water, and left there five minutes, and turned once in the time, so it shall be sure to be all wet. It is then stretched on a bow or crotched stick and hung up to dry, the same as if it had been salted. It will dry rapidly and without dripping. The acidulated water is turned into a bottle and kept for the next rennet, adding a few drops occasionally to keep its strength good. Five cents' worth of acid would cure a hundred rennets, and may be procured at almost any drug store. The scent of the acid will escape in a little time, and with it will disappear the peculiar odor of the rennet. In soaking, they are treated as if cured with salt. A single rennet cured with acid and used alone, curdled the milk for 640 pounds.

After a temporary adjournment, the convention met again in the evening, and listened to an address by Professor G. C. Caldwell, of Cornell University, on "Fermentation and Putrefaction." The subject was treated at great length and in a thoroughly scientific manner; we can only refer to one or two of its more practical applications. It was shown that fermentation depends on the presence and development of extremely minute organic particles of the nature of fungi; that they were found in milk, and when developed and multiplied, were the cause of its souring and further changes; that they existed also in the air, and were readily absorbed; that they were given off by putrescent or decaying matters, which, hence, tended to induce a similar change of

inorganic matter in their neighbourhood. Certain conditions of temperature, etc., were favourable to the development of these fungi. A Swedish physiologist, Alexander Muller, in the course of experiments with milk, had found that milk was most ready to turn sour at about blood heat, or 98° Fahrenheit—that a temperature either above or below that retarded the souring, but that at a higher temperature, another kind of change took place, one result of which was a disagreeable putrefactive odor; that rapid cooling of the milk to near the freezing point (32° F.) before putting it into the milk room, kept it sweeter; in his experiment it remained sweet twice as long as the other portions which were simply allowed to cool down gradually to the temperature of the milk room—50° to 55° in one case, and 60° to 61° in another. Again, he found that the milk turned sour much more rapidly in closed than in open vessels. In an experiment, he put the milk in two vessels on a stove when its temperature rose to 75°, one of the vessels being closed and the other open. The cream and milk in the open vessel were perfectly sweet after twelve hours, while in the covered vessel, not only were both sour, but a disagreeable odour like that of sweat was emitted; this result shows that if pure sweet milk is essential to success in the manufacture of cheese, the practice of transporting milk warm from the cows is injurious—and if it could be cooled down to near the freezing point before putting it into the cans, less harm would result from confining it in closed vessels while moving it to the factory, and that by all means it should be kept as cool as possible from the time it leaves the cow till it goes into the vats of the cheesemaker. The preservative power of a free exposure of the milk to the air was repeatedly proven by Muller; he found that the shallower the vessel in which the milk was allowed to stand, the longer it would remain sweet; and that, moreover, if a current of atmospheric air or of oxygen was forced through the milk immediately after it was drawn, it remained sweet longer than other portions not so treated.

There are conditions, however, in which exposure to the air, containing as it does the germs of fungi, will bring about the very change under consideration. Then it is known that if the milk is boiled, the organism already in it will be destroyed, and if you protect it from direct exposure to the germs of the fungi in the atmosphere, in a flask whose mouth is closed by a ping of cotton, it may be kept unchanged as long as you will. On the other hand, boil it and expose it to the air again, and it will be found that the souring is retarded—but only retarded.

The speaker then, at considerable length, considered the action of rennet as exemplifying another phase of the existence and development of these minute organisms or fungi, and traced their history in the process of coagulation and the subsequent stages of curing and ripening cheese.

After the delivery of Mr. Caldwell's address, a petition to Congress for the removal of the tax on cheese was submitted and approved, and the first day's proceedings were brought to a close.

SECOND DAY'S SESSION.

The proceedings of the second day commenced with the reading of a paper on ergot, by Professor Prentiss. This was an elaborate and able essay, in which the topic was very fully treated, and illustrated by numerous diagrams and drawings, showing the structure and growth of vegetable fungi, of which the several species of ergot were varieties. The Professor pointed out the poisonous effects of these fungi as exemplified in ergot of rye, on the human subject, and, as he believed, of ergotized grasses on cattle, producing the most intractable cases of abortion. The remedy against this disease of plants can only be sought, in our present imperfect knowledge of the subject, in the general principles of good cultivation; and with old meadows or pastures the best plan would perhaps be to break them up and reseed.

Mr. Lyman, of New York, next gave an address on butter, the very great difference in the quality of which he aptly compared to that of Jeremiah's figs:—

"Those that were good
Were excellent figs;
Those that were bad
Were not fit for the pigs,"

He showed samples of Philadelphia butter, and gave some account of the method of preparing this choice article. A brief abstract of this process has already been given in the report of Mr. Willard's address before the Canadian Dairymen's Association. Mr. Lyman believed that it only required care and attention for any farmer to produce as good an article as the best Philadelphia butter.

Mr. Webb gave a lengthened address on the trade in dairy products during the past year. He showed that the consumption of cheese in America was largely increasing, and its quality was, on the whole, much improved. In England, he believed, deterioration rather than improvement had marked the operations of cheesemaking, and English dairymen were waking up to the conviction that to hold their own they must adopt the factory system. He recommended the use of Nicholl's English fluid annatto to give the favourite colour. He also alluded to the importance of using stronger boxes than were sometimes employed in shipping. He felt sure that there was no fear of over-production so long as a really fine cheese was manufactured.

The next paper read, after some matters of business, was by Mr. Bartlett, of Ohio, on the "Soil, climate, vegetation and water of the principal dairy regions of America." This paper, as well as the others read before the Convention, will be given in full in the forthcoming official report of the proceedings, which we recommend all interested in the subject to procure.

The prize essay on "Cheese as an article of food," was read by the writer, Mr. Arnold, of Ithaca. This was a very able paper, written in a scientific spirit, and gave ample evidence of the wholesome character, convenience and economy of this valuable contribution to our dietetic resources, the advantages of which are thus summed up:—"Besides being, when properly used, a wholesome and nutritious diet; besides being richer in nutritious value than butcher's meat, or any other animal food; besides its peculiar ability to enhance the value and improve the healthfulness of other food with which it is consumed; besides the aid it renders in digestion, its readiness for use at all times without loss or trouble in cooking, its convenient form for handling and transporting; the ease and certainty with which it may be preserved for many months without loss or injury, all commend it to the favour of the public, and especially to the army and navy where it could not fail to prove not only a luxury to our soldiers and sailors, but a cheap, healthful, and substantial substitute for the continued use of salt meat."

The proceedings terminated with a resolution that the next Convention should occupy three days, and the objects of the association be so enlarged as to embrace the subject of butter.

Vermont Dairymen's Convention.

The first meeting of the Vermont Dairymen's Association was held at St. Albans, commencing on the 19th of January and lasting over three days. The proceedings were opened by an address from Hon. E. D. Mason on the benefit of associated effort in Agriculture, as exemplified especially in the dairy interest. He was followed by the Hon. Henry Law, who read an able practical essay on the dairy, advocating among other things the use of sugar beet as food for milch cows. In the evening of the same day, an address on the factory system and dairy management was delivered by X. A. Willard, Esq., who stated that in New York State there had been during the year 1869 over thirty millions of pounds of milk sold, the value of which at four cents a quart would amount to nearly five millions of dollars. The cheese produce of 1869 Mr. Willard estimated at 240,000,000 lbs., and the butter product at 700,000,000 lbs, both together representing a value of $215,000,000. On the second day, Dr. Middleton Goldsmith delivered an address chiefly on the breed and management of dairy stock. This was followed by an paper by Hon. G. D. Alvord, on salt and its uses in the dairy. The afternoon session was opened with an address by O. E. Hubbard, on the breeding of dairy stock. The principal business of the third day was the reading of a paper on Grapes, by Mr. Richard Goodman. All the meetings were well attended.

Dairy Meeting.

A dairy meeting was held in Markham on the 7th of February, when the following questions were discussed:—

1. The comparative profit of dairy farming, and its advantages in maintaining the fertility of the soil.
2. The selection and feeding of dairy stock to secure the largest amount of profit.
3. Cleanliness of the dairy, operations, utensils, and healthy cows necessary to the production of good butter or cheese.
4. The advantage of selling the milk at the farm over that of making butter, considered with a due regard to the value of the whey and skimmed milk.

The chair was occupied by Mr. J. Gibson, the President of the East Riding of York Agricultural Society. The meeting was largely attended. The chairman opened the proceedings in an appropriate speech, and was followed by Hon. D. Reesor, H. P. Crosby, M. P. P., J. Trann, J. Pike, and others.

The benefits of a mixed system of husbandry were advocated and illustrated by most of the speakers, and the peculiar advantages of dairy farming were especially set forth.

Mr. Trann stated that he had kept an accurate account of the amounts realized from his cows yearly during the past three years. From eleven cows in 1867 he realized $600; from twelve cows in 1868 he realized $772; and last year about $850 from thirteen cows. These amounts include butter, cheese and calves sold during each year.

The great benefit derived from feeding green corn, and the use of the dried fodder from the same during winter, were attested by several speakers, and the more general cultivation of these crops on dairy farms was strongly advocated.

Cheese Factories.

J. K., Harper P. O.—You will find an article in the CANADA FARMER of December, 1869, on this subject. If you intend to start one on a large scale, you can get much information by calling on, or writing to, Mr. James Noxon, Ingersoll, Ont. The profits will depend greatly on the facilities for obtaining a sufficient supply of milk, and the quality of the cheese manufactured. Last year the business was a very profitable one in good hands. But little, if any, more expense for materials and labour would be incurred in a factory using the milk of 500, than one using that of 300 cows. Small factories are not proportionally as profitable as large ones, though they may be made so, where the proprietor does the work of manufacturing the cheese and can keep a large number of cows of his own, and buy the milk of his neighbours at a reasonable price. Calculating that ten pounds of good new milk will yield one pound of cheese, which is about the general average, and the value of the cheese at twelve and a half cents per pound, new milk would be worth about one cent per pound delivered at the factory. At this price the farmer would make more by selling his milk than by keeping it at home for the sake of the butter that could be made, unless, indeed, he has cows that give an average of over eight pounds of butter each per week, for the whole season.

In making calculations for the purchase of milk to supply a factory, it must be made a certainty that the milk of an adequate number of cows can be secured for the entire season, without fail, and each one who agrees to supply milk must stipulate to furnish all he obtains from the number of cows he agrees to supply the milk of, from the beginning to the end of the season of cheese-making. Usually one or two cows are reserved by each patron to yield a supply of milk and butter for his own family; but while he cannot have the privilege of withdrawing any cows, the factory man is always willing to take on more, as the patron has them come in, or as new patrons wish to join. The annual report of the Canadian Dairymen's Association, which can be had from Mr. James Noxon, Ingersoll, by any one joining the Association and paying their annual fee, $1, will give a large amount of interesting information on the subject of cheese factories and cheese-making.

Butter Factories.

In view of the now acknowledged fact that the establishment of cheese factories has done so much to improve the quality and increase the consumption, and therefore the value of cheese, it may be well to consider the necessity and feasibility of improving the quality of butter through the means of associated capital and effort, directed toward the establishment of butter factories. Notwithstanding all that has been said in the agricultural press on the subject of making butter, and the extra inducement offered in the way of higher prices for a really good article, there does not seem to be any general improvement in the quality of the butter sent to the leading markets of America. So far from improvement being the order of the day in this article, we are afraid that quite the reverse is the case.

To hard-working farmers' wives, a butter factory in their neighbourhood would prove a boon. It would be the means of lessening their labours greatly, while still enabling them to make money out of their dairies. It would also prove beneficial in another way, namely: encouraging the farmers to pay more attention to breeding stock, with a view to securing cows that would produce milk rich in quality as well as great in quantity—also in leading them to see the advantages of improving their pastures, with the object of keeping a larger number of cows on the farm. Under the present system of making butter at home, the ability of the farmer to profitably stock his farm is frequently curtailed by the impossibility of having more than the products of a very limited number of cows properly attended to.

The best plan to be followed in establishing a butter factory has yet to be discovered by the results of experiment, but in any case it would require much less outlay of capital for materials and costs of management than is necessary to start a cheese factory. There are two courses open to be followed. One is for several farmers in a neighbourhood to club together and start one, each supplying the milk from his cows, to be set and manipulated at the factory by a skilful dairymaid, the proceeds of the butter produced to be divided according to the quantity of milk supplied by each. This plan, however, would present many difficulties.

The other is for a person to start the factory with his own capital and buy the milk from the farmers, the price being regulated by the quality and richness of the milk, which can be ascertained by a lactometer. In this case the factory man would take the whole responsibility upon himself. He would require to visit occasionally each of those from whom he bought milk to see that the cows were healthy and properly managed, rejecting the milk of those who allowed their cows access to bad water and pastures overrun with weeds, or who treated them in a manner likely to make their milk prove injurious to the interests of the factory.

The milk could be brought to the factory either by the patrons or by the factory man, as might be most desirable. The churning of the cream, and even the working of the butter, could be done by machinery. A good supply of ice and a good spring of pure cold water would be necessary, and with all the details of management under the care of an experienced person, success in producing a first class article, that would command a ready sale at high prices, ought to become nearly a certainty.—*J. M. in Country Gentleman.*

Ohio Dairymen's Convention.

The Ohio Dairymen's Association held their sixth annual convention at Wellington, in Lorain County, on the 26th and 27th of January. Wellington is the centre of an extensive dairy district, and next to Little Falls is one of the largest cheese markets on this continent. During the last season, we are informed, nearly 4,000,000 pounds of cheese were shipped from this Ohio market. The Convention was of a very interesting and instructive character, the various addresses being carefully prepared and the discussions animated. The chair was occupied by Hon. A. Bartlet, the President of the Association, who opened the proceedings by an appropriate address. Among the subjects discussed was that of floating curds, the cause of which was generally admitted to be tainted milk, and the cheese manufactured from such was justly considered deleterious and unfit for food. Regarding the delivery of milk once or twice a day there were different opinions; but the meeting passed a resolution in favour of delivering once; and also recommending that the milk should be cooled before being carried to the factories.

The subject of pastures, and the bad effect of foul weeds, was ably treated in a paper by Mr. A. C. Benedict. The annual address was delivered by the Hon. G. Willams, of Oneida County.

The principal business of the second day's session, after the nomination of officers, was a discussion on Sunday cheese-making, in which papers on each side of the question were read, followed by a warm discussion, which resulted in the adoption of two rather conflicting resolutions—one endorsing the practice as a work of necessity, the other recommending that, whenever practicable, the milk should be kept over till Monday. Papers were read on milk fever and on rennets. A petition was adopted praying for the exemption of dairy products from tax on sales.

Poultry Yard.

Management of Peafowl.

My peahens lay twenty-five eggs each during the summer. Their eggs and the cock's feathers are worth more than their keep. I find them do best in a good sized aviary.—There is no comparison in the number of young birds that can be reared in one season by keeping them up and taking their eggs, rather than allowing them to hatch and rear their own. I prefer setting their eggs under a large fowl, as they can be more under control when so hatched. This is quite at variance with old notions, yet quite true. In every case they require a considerable quantity of green food. I give large quantities to my pigeons. I cut a cabbage with a long stalk to it, and put it into the neck of a bottle with water in it; this keeps it fresh. My pigeons eat it greedily, and are always in health. I am particular as to their food and water being clean, and often have the room whitewashed.—*London Field.*

A Spring Poultry Show.

To the Editor.

Sir,—I met a gentleman to-day at the poultry sale, who stated that he had been led to infer, from a late communication of mine in your paper, that the Ontario Poultry Association was on the decline, and that, consequently, several gentlemen, in his neighbourhood, were hanging back from joining.

It was certainly not my intention to give this unfavourable view of the *status* of the Society, which has lately added several new members to its list, and has revised all its rules and bye-laws. Several gentlemen connected with it have combined and sent orders to Europe for thirty dozen eggs, and the interest manifested at the sale to-day does not give the idea of any decadence in the poultry fancy.

The prize list and rules for the fifth exhibition are merely waiting to be put into the hands of the printers, and some $120 above the sum required for the prize list is on hand. The committee have the following questions under consideration as regards an exhibition:

The first is, as it cannot be held before the 18th of April, many say it is a bad time; and so it is, the hens being at maternal duties; but it is a period of comparative leisure, and perhaps the most convenient for visitors.

The second matter is a question of funds About $400 is required to be guaranteed for the coops, which are to be portable, and will thus constitute the show perpetual, as the money for prizes can always be had, and the coops, being portable, will always be on hand, and may even be hired out to other societies if required.

It therefore rests entirely with those fanciers who desire an exhibition to come liberally forward *without delay* with donations and subscriptions, and the difficulty will disappear.

F. C. HASSARD.

Toronto, Feb. 19, 1870.

Fowls vs. Worms.

M. Giot, the French entomologist, has lately found new employment for fowls. He says that French farmers have, during the past year, complained bitterly of the prevalence of worms which infest corn and other crops, the highest cultivated fields being the most infested. Fowls are known to be the most indefatigable worm destroyers, pursuing their prey with extraordinary instinct and tenacity. But fowls cannot conveniently be kept upon every field, nor are they wanted there at all seasons. Therefore M. Giot has invented a perambulating fowl-house, which is described as follows:

"He has large omnibuses, fitted up with perches above, the nest beneath. The fowls are shut in at night, and the vehicle is drawn to the required spot, and, the doors being opened in the morning, the fowls are let out to feed during the day in the fields. Knowing their habitation, they enter it at nightfall without hesitation, and roost and lay their eggs as well as in any other house."

Sale of Fancy Poultry.—An auction sale of poultry took place in this city on Saturday, February 19th. The birds were advertised as "imported," and drew together, in consequence, a large attendance of poultry fanciers, some coming from a considerable distance; but there was very little merit in the collection, the majority of the lots being of inferior quality, and in poor condition. The prices realized were not such as to encourage the repetition of the experiment, ranging from $1 to $2.70 each for poultry, and from 30 cts. to 70cts. for pigeons, of which there were only a few ordinary specimens. Good birds with such an assemblage of buyers would have fetched very different prices. The lots, with the exception of a few of cohchins belonging to Col. Hassard, were none of them, we are authorized to state, the property of any breeder of note connected with the Poultry Association.

Water for Fowls in Winter.—One great difficulty with poultry in the cold winter weather, is the constant freezing of the water left with the fowls, and consequent adhesion to the vessel containing it, thereby causing much trouble in continually throwing it out. There is, however, a very simple remedy by which almost all the trouble can be saved—namely, to thoroughly grease the inside of the pan or dish in which the water is placed, and in freezing no inconvenience from adhesion will be found, as in moving the pan or dish it will at once part with its cake of ice, and so entirely obviate the necessity of placing the vessel on a hot stove to thaw.

C. D.

Correspondence.

Steam Cultivation for Canada.

To the Editor.

Sir,—A few words on the steam plough, as it has been, is, and ought to be, may prove instructive to some and interesting to others of your readers.

There are three considerations that have brought about the successful employment of steam as a tractive power for the plough—they are, speed, cost and efficiency. How far have these points been gained? As regards speed, success has been reached so far that where good systems are used and the work is well laid out, an acre of strong soil can be turned up in ten hours to a depth of eight or ten inches for each horse-power expended. In the matter of expense little has been gained, as so much of the work hitherto done has been by way of experiment that only a few have realized a saving in the cost of the operation, though the superiority of the work has been a fruitful source of profit. In regard to efficiency, steam is eminently triumphant. The greatly increased aeration of the soil worked by steam is become so well known as to be admitted by all, friends or foes to its progress. Steam-worked land has no pan, and water seldom stands on the surface. The one great object of most steam-users is to keep all possible weight off the surface, except when the operation of breaking down clods is necessary, and the present systems of steam cultivation require no weight but that of the implement to traverse the land to be tilled. This is one main reason of the land lying so very light. Some even drill the seed by steam power, at a cost greater than that of the same operation when performed by horses, for the simple reason that horses' hoofs inflict irreparable damage to any land in a fit state to receive seed.

Thus, it will be seen that a successful steam cultivating apparatus must be able to work quickly, cheaply, and without compressing the land.

Now, as the chief part of such apparatus is the engine—other parts only being made to suit it—let us consider what kinds of engines have been and are used, and what are the kinds that will and must come into use before steam can be generally used on American farms.

One system that has found much favour in some parts is called the "round-about." To work this any kind of engine is used. The traction ropes pass round sheaves at the corners of the field, and on the headlands, drawing the plough to and fro, while the engine is stationary. The only advantage this system has is that it keeps the horses off the land. It requires much manual labour, and is as costly as horse work. This system is quite different to American ideas of efficient machinery, and few here would have patience to work it.

There is the "anchor" system, in which the engine is locomotive, travelling one headland, and its traction ropes pass round the sheave of an "anchor," moving parallel on the other headland, as the work progresses. This system, improved, on properly prepared farms, might pay well here, but as it requires some time to shift from field to field, will not do for general use.

The last system remaining to be noticed is the "double-engine," which is the most recently introduced, capable of doing most work, taking fewer "hands," and the one able to work most efficiently and under the greatest variety of circumstances. Two engines are used, moving parallel, one on each headland. These draw the plough backward and forward between them, in turn, and while one draws the other can have its machinery attended to, "firing up" done, and be moved forward for next furrows. Very little loss of power, economy and handiness are great recommendations to the use of this system, over others. The main drawbacks it has are: the headlands, necessarily left unbroken, to facilitate work; and the unwieldy character of the engines that have been used; also, the first cost prevents many from introducing them.

Steam ploughing heretofore has been too tedious, inapplicable to a majority of farms, or the machinery has been too cumbersome and expensive.

One system proposed, and largely believed in by many, especially in America, is that the engine should draw the plough after it horse fashion, or that the engine and plough should be combined. The first cost of the apparatus would be little, compared with some systems, but, supposing there were no other objections, the working expenses would not be nearly so low. The engine would consume a large proportion of its power in continually moving itself (besides the great additional wear and tear incurred) against which there is no set-off in the double engine system. Fuel and water expenses would be increased, and time would be lost in lubricating, receiving the wood and water, and in turning at the ends. But the main reason that such a system could not succeed is, that almost as much harm would be done by the engine moving over the land to be worked as the operation would do good—the particles of earth would be so solidified that several operations would hardly eradicate the effects on the top soil; yet the greatest damage would be below. The drains, at a depth of thirty-two inches or more, are generally blocked wherever an ordinary ploughing engine has passed over, if the land is at all damp at the time; and the continuous use of heavy engines would soon produce an impervious pan. This system has been tried over and over again, and has hitherto failed, not because suitable engines have not been tried, for many such have been produced, at immense expense, but from the above practical difficulties. Some may say, try a light steel boiler and one of Hamilton's small rotary engines. Such would be an improvement, but the first objection urged against the system would hold good. That an engine might be constructed to work on this system at an equal cost to similar work by horses, is certain, but where would the gain be? Horse flesh is the cheaper apparatus.

The system that will probably succeed eventually in America—for steam must come—will be either the double engine, improved, or the twin engine, perfected, system (in which both engines apply power simultaneously and continuously to the same implement).

Many improvements have recently been made in steam engines, and are about being introduced, which will enable engines to to be built much cheaper, to work, on the two systems last named, with greater success than has been yet reached.

The great defect in all ploughing engines hitherto constructed has been that no dome could be placed on the boiler, for want of room. This Hamilton's engine wholly remedies, and also simplifies and lessens the necessary gear. Engines combining late inventions could perform all ordinary farming operations much cheaper than can be done by horses; they would be so simple that any one could work them; handy enough to turn into any common gateway; be equally available for traction purposes on ordinary roads, threshing, &c.; could pass readily over soft wet ground; and the sum for which they might be manufactured would be less than that of those at present employed.

There is now no real obstacle to the general use of steam farming machinery, and the capital taken to work any ordinary business would purchase and run such as described.

R.

Economy of Time.

To the Editor.

Sir,—It seems strange that men that have lived to the age of sixty, fifty, or even forty years, will lay out their farms and buildings to such disadvantage. It seems that they have no new ideas of their own, but do as their fathers and grandfathers did.

A person in travelling over the country sees many farms, and all differently laid out; and it really looks as though the owners laid them out so as to make plenty of work for the women and hired men.

Men who move on new farms in the woods are to be excused; for the first thing needed is a house, and that is built near the road, on a rise of ground, (if there is any to be found). But it is not necessary to have the barn sixty or eighty rods from the house, for fear of taking fire from the stovepipe, and the stable as far from the house in another direction.

If people would think a little, and talk the matter over with their neighbours and ask their advice, they would hit upon some new ideas by which they could have things more convenient, and save hundreds of miles of travel, which is quite a consideration, especially when it is muddy, or the snow deep. I know a farmer who has three different places, each forty rods or more apart, where he has to go to feed. One is near the house, another forty rods from the first, and the third forty from the second in another direction. Now, this farmer is always behindhand with his work, and always in a hurry; he keeps one or two hired men. He has but one gate in use on the two hundred acre farm; he had some new ones made about three years ago, but he keeps them in the old house out of the weather. I think it must be a pleasure to him to take down and put up the bars.

I know another farmer whose well is about fourteen rods from the house, and his cattle had to go about half a mile for water or go without.

I know of three men living on a rented farm, and they carry all the water for the house use from a neighbour's about forty-five rods distant. They have been living there over two years, and they must go on an average about once each day. Now, let us see what it amounts to; say, one man forty-five rods and return makes ninety rods; three times ninety (for there are three families) makes two hundred and seventy rods, multiplied by three hundred and sixty-five makes about three hundred and eight miles per year. Just calculate how long it will take a man to walk three hundred and eight miles: even at the rate of thirty miles per day it takes over ten days.

Let us set against this the cost of digging and curbing a well, say, for digging, two men, one day..... $2 00.
Lumber, say 200 feet, (that is plenty). 2 00.
Nails..... 05
Other work..... 1 00.

Whole amount..... $5 05.

Perhaps this is too low an estimate. The labour of two men might be required, one to dig and one to haul away the dirt, for more than one day; still, the expense is seldom considerable.

By this you can see how some men spend a good part of their time, and yet they cannot see why they do not get along better. There might be many instances of the kind enumerated, but the above is enough to set those who have any brains to thinking.

L. R.

The Engineer on the Farm.

To the Editor.

Sir,—Steam and mechanical expedients are rapidly being brought into subservience to the ends of the husbandman. On this side of the Atlantic we use machinery much more largely for some agricultural purposes than it is used in Britain, whilst for other farming processes mechanism is much more employed by the old country farmer than by our own. This is natural, and almost a necessity, considering the needs and position of America and Britain. There are many ways, however, in which we might, with advantage,

use English agricultural devices. For instance, the English seed drills.

Steam is beginning to be used to a much larger extent in British farming than ever, not only for threshing, etc., but in many parts the plough is quite successfully worked by this means, and on one farm we know of, not only ploughing, but all the tilling is by steam, cultivating, harrowing and drilling the seed included. It may not, perhaps, be practicable to bring the steam threshing machine or steam plough into common use in Canada just yet, but there is a way steam could be made greatly to benefit us,—by applying its unlimited powers in lieu of the axe, in clearing our interminable forests. This seems a new proposition, and presents many difficulties; but in an engineering point of view it is quite simple, easy of accomplishment, and an ordinary operation, Machinery, peculiarly adapted to the purpose is largely in use in England in other ways; the capital to purchase this is the only real difficulty.

"How would you go to work?" perhaps some one asks. Simply to pull down the trees, or pull away the stumps.

Our old settlers, who have spent many a weary day in chopping out a clearing, would no doubt be inclined to ridicule the idea, at first. Let them, however, think of the many giants they have seen lying prostrate, uprooted, from the simple force of the wind. Considering what leverage the trunk of the tree offers the engineer as a means to extract the roots from the ground, it will be perceived that he would simply have to attach a steel rope or chain to such part of the tree as he deemed most advisable, and haul it down and away to any desired place.

I have no doubt but that this will sometime be the way the clearing of the forest will be performed, and the sooner the better for many. Machinery for this purpose could also be employed for sawing, grinding, ploughing, or any other purpose of the farm. The expense incurred in working would simply be interest on capital, and the time of from two to six men; giving a large return from receipts for work accomplished. Other ways of using engineering knowledge on the farm suggest themselves; but, for the present, I will only throw out the above suggestion as one that appears to me to be feasible and profitable.

R.

Broom Corn.

To the Editor.

SIR,—Will you be kind enough to inform me, through the columns of your journal, if it would be possible to grow broom corn in the vicinity of Hamilton. I presume we could raise plenty of stocks, but could we successfully grow it so as to insure its perfect heading? I have been informed that the broom itself does not attain a sufficient length for manufacturing purposes, and if this is the case, of course it is useless to raise it. I would also like to know what soil is best adapted for growing it, whether the ground should be very rich, and also what yield could we expect per acre.

JOHN W. SMOAK,
Hamilton, Ont.

REPLY.—To grow broom corn successfully, the same climate, soil, and general culture are required that are suitable for the large Western corn, or for the Chinese sugar cane, which last is simply a variety of broom corn (*Sorghum*). As, however, it matures earlier than the large corn of the West, and should be cut for economical purposes before the seed ripens, it is quite possible it may be adapted for some of the warmer portions of this Province, and at least the trial is worth making; though from the nature of our climate it would probably be an uncertain crop, and only answer in very favourable seasons. Rich loamy soils, not stiff clays, are most suitable. About 500 pounds to the acre is considered a fair average yield.

Advertisements for the "Canada Farmer" must be sent in to the office of publication early, and in order to secure their insertion in the forthcoming number, must in no case be later than the 7th of the month.

The Canada Farmer.

TORONTO, CANADA, MARCH 15, 1870.

Agriculture and Arts in 1869

The report for 1869 of the Commissioner of Agriculture and Arts, for the Province of Ontario, has been issued with commendable promptitude, and contains a large amount of interesting information. We noticed the report itself at the time it was laid before Parliament; but the statistics contained in the various appendices deserve more than a passing remark. These appendices are five in number, and may be referred to in their order.

The first contains an analysis of the reports of the various agricultural societies for 1868, so far as they have been sent into the Bureau. As a general thing, these reports have been made out in a very clear and satisfactory manner, and show, according to the Commissioner, a very great improvement on former years. Of course, some are not all which could be desired; but, upon the whole, they are very encouraging. There is an increasing desire and effort to improve the local exhibitions, by having fewer of them and amalgamating for this purpose two or more of the existing associations. No doubt this is a move in the right direction, especially when efforts are being put forth, along with the exhibition, to improve the breed of the various domestic animals by the Societies purchasing superior animals for stock purposes, and introducing for purpose of trial, new and improved seeds. From such a mass of reports, it might seem invidious to select one or two of marked interest and excellence. Considerable activity and interest seem to be manifested in the District of Algoma, for instance, though one of the newest and least advanced districts of the Province; while the older districts, not contented with the degree of excellence already attained, are with praiseworthy earnestness seeking to make still further advances. The continued growth of wheat for successive years, on the same land, is being dropped by an ever increasing number, injurious as it is in the long run to all concerned, though for the first few years apparently profitable. The report from South Brant well says:—"It cannot be sufficiently published for the benefit of all the great gain which may be made by adopting a judicious system of rotation, the growing of green crops, roots and vegetables." With good farming, Ontario may be made a garden. What bad farming can accomplish is testified by thousands of "lean and hungry" acres almost everywhere, which, once rich, now scarcely afford a wretched subsistence to their unskilled and thriftless proprietors. Sometimes people are foolish enough to try to excuse their bad farming by saying that they can't afford to do better. If good farming won't pay, bad farming need not be tried.

The conclusion of this report from South Brant is worth giving; and its sentiments ought to be impressed upon the minds of all who have the best interests of Canada at heart.

"We therefore say, educate your sons and daughters; never cease, in season and out of season, to impress upon their minds, the nobility, dignity, yes! the blessedness of labour; the Godlike virtue of truth; the necessity of honesty and liberality in their dealings with all men. Purchase books, old and new, for the use of your families; spend less in adorning the person, more upon the mind; more usefulness, less worthless display. Place the minds of your sons and daughters, by means of books, in direct communication with the best minds that have lived during the last three thousand years, and thus endeavour to make the rising generation, giants, mighty men of renown, who will go forth into the world to make their mark as artizans, mechanics, chemists and farmers; men who will be eager to aid industrial progress of every kind, to help forward a new social organization, having for its object the banishment of poverty and distress from the face of the land, together with other much needed reforms; then, after a lifetime spent in usefulness and self-abnegation, in doing good and helping their weary, toil-worn fellowmen, "they will leave behind them honourable names to be remembered with those of the benefactors of humanity."

The second appendix has reference to Mechanics Institutes.

According to the new law passed by the Local Legislature a dollar a year is given by Government for every dollar raised by Mechanics' Institutes for evening instruction, up to a maximum of two hundred dollars. Thirteen Institutes availed themselves of this provision in 1868, though only three of them received the maximum. Among these thirteen $1,610 were distributed. Last year seventeen Institutes received grants, and had $2,356 07 divided among them. Of course there is a large number of other Institutes which have received no grants. Some of these seem to be in a very flourishing condition; others are rather languishing.

The Report of the Fruit-Growers Association will well repay a careful perusal, abounding as it does in useful suggestions and interesting facts.

The crop returns given in appendix 4th will be very useful to compare with those of coming years. While there have been partial failures in certain localities, in general the crop of '69 is much above the average. In many places the yield is given as double that of the previous year, while one-third, or even one-half more is not uncommon. The average yield of Fall Wheat in 1868 was 20½ bushels per acre; in 1869 21¾. Spring wheat in the former year averaged 14 bushels; in the latter, 19¼. In 1868 oats averaged 24 bushels; last year, 30. Barley in 1868, 22½; in 1869, 30½. The highest yield of fall wheat in 1869 was 28 bushels per acre. Of Spring, one county gives 30 bushels per acre, but generally from 20 to 25. Oats in some cases reached a yield as high as 50 bushels per acre; and 35 and 40 were quite common.

We hope the reports of succeeding years will be much fuller, and give even a more satisfactory view of the agricultural condition and advancement of our fair and fertile Province. Much has already been done, but a great deal more remains to be accomplished; and we sincerely trust that all will do their best in a work which has so intimate and influential a bearing upon all the best interests of every class of the community.

No country can flourish where agriculture decays, and by way of eminence this is true of Ontario. Whatever facilities we have for developing manufactures—and these are great—such industries must always occupy a secondary place compared with utilizing to the utmost the resources of our fertile soil.

Agricultural Societies.

So thoroughly has the spirit of improvement now taken hold of the farmers that there is scarcely a county or township in Canada but has its Agricultural Society, and judging by the numerous reports of their doings the past year, as given in local papers, they seem to be steadily progressing in the work of increasing the interest taken by the rural population in the advancement of agricultural knowledge, and the improvement of the productive capabilities of the soil, as well as increasing the value of the stock raised on their farms.

Our limited space forbids giving any extensive notice of what is contained in the several reports that come to hand, as where all are striving to do their best, it would appear invidious to give prominence to a few of those that appear to have met with the greatest success in their efforts.

We were pleased to notice, in the cases where we attended agricultural fairs last autumn, that the matter of selecting competent judges, and judiciously arranging the prize list so as to give encouragement to individual effort in introducing improved stock, and better implements suitable to the wants of the farmer, was beginning to be appreciated.

There is one point on which the officers of the societies do not yet seem to place sufficient stress; viz: punctuality on the part of the exhibitors in getting their articles on the ground and properly arranged in their places at an early hour, before the time comes for the general public to be admitted.

There is too much latitude allowed to exhibitors in this matter, and as in most cases the fairs are now extended to two days or more, it will be well to insist on a close observance of the rules of the society, and in time the people will become educated up to a knowledge of the value of punctuality. A thorough classification and proper arrangement of all the articles on exhibition, placing each class in a division by itself, and affixing thereto a proper label in letters that "one who runs may read," is a very great help towards bringing those who attend the fairs to observe and compare as well as see; for one of the great points aimed at in agricultural fairs should be to evoke a spirit of observation that will lead men on the right path towards improvement.

We might suggest that it would be well for the directors of one agricultural society to correspond with those of another, through their secretaries on the matter of appointing judges, and by this means an exchange could be made between them of men thoroughly competent. For instance the directors of a township society could either be appointed the judges at the fair of an adjoining township, or could give their brother directors of that township a list of those persons who in their opinion were likely to prove acceptable as judges, and at the same time had the advancement of the interests of agriculture sufficiently at heart to induce them to sacrifice a little of their time to so laudable an object. So with county societies. One object to be gained thereby would be the saving of expense, while insuring punctuality; for in cases that have come under our observation, judges have been appointed to attend at fairs, who resided at such distant points that they could not possibly attend except at great personal inconvenience and expense, which in all cases it is desirable to avoid imposing on men who take a real interest in agricultural progress.

Farm Labour.

It is much to be regretted that the old country system of employing labour on the farm all the year round, is not more generally adopted here. It would be better for both the farmer and the labourer he employs, if instead of our plan of hiring by the month, and then only during the season of actual tillage operations, and boarding at the house, men were hired by the year, and provided with a small cottage and garden. In this way not only would labour be cheaper, as a man will hire by the year at a much lower rate; with a certainty of employment, than if paid by the month for a short time, but it would bring a better and steadier class of labourers into the country.

What is needed is that farmers should give encouragement to married men with families to settle in the country. As things are now, the generality of farm labourers are either young men, sons of farmers, who would be in a better position if married and settled on farms of their own in the back country, or of that shiftless class of half mechanic, half la-

bourer, commonly found hanging about the skirts of towns and villages, always on the look-out for a job, that they often tire of and abandon when half done.

The right class of men are agricultural labourers—men that understand ditching, threshing, &c.; and such men can be got if they are given encouragement to come to the country.

A man of that kind, even with a family, can live and thrive on $120 a year, and board himself, as a garden patch of half an acre, with pasture for a cow, or milk given from the farm house, will give him all he needs except meat and flour, which the farmer can supply him with at market prices.

Under this plan there would always be a man on the place to do the chores when the farmer himself was busy. He could be employed in winter in threshing oats or seed grain with a flail, cutting up a supply of firewood for summer, and even digging ditches for underdrains, if proper preparation had been made the previous fall for carrying on that work. The comfort and profit of having such a man ready at all times for any kind of work needs only to be experienced to be appreciated.

Emigration to Canada.

We are glad to notice on every side evidences that Canada is attracting increasing attention in Britain as a very desirable country for the industrious and struggling poor to emigrate to. As the result of this, much more correct ideas are being diffused in regard to what sort of a place this Canada is. Even the Thunderer of Printing House Square condescends to give the Dominion a patronizing pat upon the shoulder and the information about the position and capabilities of the country are not at all so absurdly apocryphal as it used to be even a short time ago.

The Cottager and Artizan, for instance, a very nicely printed and illustrated paper which circulates largely among the working classes, has begun in its January number a series of papers on Emigration, for the purpose of advising who should emigrate, and to what countries they should go. It gives, in the first place, some account of the Dominion, and comes passably near the size of our promising country. The dimension of the whole Dominion it puts down at about 15 thousand square miles less than that of old Canada alone. New Brunswick and Nova Scotia, however, contain 47,200 square miles; and if the 15,000 of deficit be added to these, this friendly informant tells the working classes of England that the Dominion has 62,200 square miles of territory less than it actually has, to say nothing of the North-West at all. Well, when the people of England get within 60,000 square miles of the true area of any British possession, a great step has been made. Things in that case will get into shape by and by. Though the writer of the papers in question is not quite accurate about the size of our country, he writes in a most friendly spirit, and gives good advice to those who ought to emigrate, as well as to those who ought not.

It cannot be too often stated that the idle, the dissipated, the pauperized, and the skilled workman who can do only one thing well, and will rather starve than turn his hand to anything else, ought not to come to Canada. A man who comes here must not be afraid of hard work—must make up his mind to encounter a good many disagreeable things, and must be resolved to meet such things like a man. He must be ready and willing to turn his hand to anything, and avoid strong drink as he would his greatest enemy. If he do that, and keep at it, with health and ordinary care, he will find Canada a very good place for him and his. Paupers, who expect to be helped at every turn, had better go elsewhere; or, better still, stay where they are. These papers by Dr. Ford, in the "Cottager," will do good. The more the plain, unquestionable facts about Canada are known in Britain so much the better for us and so much the better also for the struggling, industrious masses in the old land. Money is not to be had for the lifting, either in town or country throughout our Dominion; but there is wealth and a reward for "honest labour," as tens of thousands can gratefully testify.

Returning Emigrants

The recent arrival in Toronto of several families from Illinois, *en route* for Muskoka, affords additional evidence of the difficulty of making a living in some parts of the neighbouring Republic. Some States which are possessed of immense quantities of prairie land and other apparent advantages, are in reality less adapted to farming than other places not apparently so highly favoured. Illinois, for instance, has land enough and to spare for all the population she can gather for many years; yet her principal city teems with men out of employment, amongst whom are many who have come in from the country. There is much to militate against their success as agriculturists. It is not the want of land, and as the complaint is made by many, there must be some cause for which the men themselves are not to blame.

The prairie lands farther North-West offer more inviting fields for farming operations than Illinois. Minnesota is far superior to the more southern States; its growth of wheat is enormous, and its climate fine.

Our own North-West Territory, by which is meant those districts watered by the Red River, Assiniboine, Saskatchewan, and neighbouring streams possesses greater advantages than any State to the south of it. The prairie land is of the most fertile kind, there is more wood at the hand of the settler, and there is a plentiful supply of coal. The country farthest west possesses a milder climate than Minnesota, and is equally wealthy.

Accounts of the resources of that portion of British North America, known as the "Fertile Belt," agree in describing the country as the finest on this Continent; and there is no doubt that when the road is open to Winnipeg a stream of immigration will set in which has never been paralleled in British America. The isolation under which the North-West has slowly thrived will be exchanged for easy and constant communication with the older Provinces. The coming spring will see numbers of Canadians settling in the newly-opened Territory, and the construction of a railway through the Settlement is not far distant.

The attractions which the North-West offers will not fail to draw many besides Canadians. The efforts which are being made in England to provide means for sending Englishmen to the Colonies will result in numbers finding their way to Winnipeg. Canada's popularity in England is greater than that possessed by any other Colony; and were our emigration interests in Great Britain attended to properly and regularly, there is little doubt that we should receive by far the greater portion of those who are leaving their homes. The prospects which the North-West offers to men of all ranks, but particularly to those who can command a little capital, are so great that, if properly understood in England, the opportunity would be seized by many who have now no thoughts of coming. The man who in England farms a small patch of fifty acres, and who is compelled to use several hundred pounds in capital, would find his means and his knowledge far better employed on this side of the Atlantic. He does not know that, however; he has only a misty idea of which is Canada and which the United States, and he would not know where to come to, if he made up his mind to come at all, without proper information being given him. There are numbers of men of another class who have just enough money to be useless in England, to whom the North-West offers a golden opportunity; and there is no lack of men, who, having one or two hundred pounds, which brings them in perhaps three or four per cent., would gladly remove to a country where their capital would, in a few years, be of a very different magnitude.

Notes on the Weather.

The winter so far has been characterized by very moderate weather, though the latter part of February has been colder than any other time of the season. Snow has been abundant throughout most of the country, there being excellent sleighing even at Toronto during a good part of the month.

Stock of all kinds seem to have wintered well, and a great demand exists for good animals, especially milch cows and heifers, which bring exceedingly remunerative rates, where well bred and in good condition.

The range of temperature for February has been considerable, though the figures indicate a slightly lower degree on the average than last year. The highest temperature was 40° 6 on the 17th; the lowest, -6° 6 on the 21st. The mean temperature of the month has been 21° 7, being 1° 3 below the general average, and 3° 3 below that of February, 1869. The amount of rain-fall has been 0.520 inches; of snow, 20.2 inches. There has been little clear weather, 17 days having been entirely overcast, and 11 partially so. The prevailing winds have been westerly, with considerable variation to the north-west and east.

Simmers' Cultivators' Guide for 1870.—We have received a copy of Mr. J. A. Simmer's annual catalogue of field, vegetable, and flower seeds for the current year. Besides furnishing a complete and well arranged list of seeds, comprising all the latest novelties, the pamphlet contains, as its name implies, brief practical directions for the sowing and culture of the various garden plants. Mr. Simmers' well established reputation as a careful and reliable seedsman, his moderate prices, and the excellence of his stock of seeds, to which we have pleasure in bearing testimony from personal experience, give him a claim to a full share of patronage both among farmers and amateur gardeners. He has recently added to his facilities for business a garden for raising seeds and flowers, which is situated a short distance from the northern limits of the city. A copy of the "Cultivators' guide will be sent to any one remitting in a pre-paid letter a three-cent stamp for return postage.

Miller's Tick Destroyer.—We have pleasure in directing attention to Mr. Miller's advertisement in refereace to his valuable remedy for sheep ticks and other vermin that often prove so troublesome to the infested animals, impairing their health, and deteriorating the quality, as well as diminishing the quantity, of their wool. This preparation has now been before the public for several years, and has steadily gained in reputation as it has been more extensively tried. It has found its way, not only over all parts of Canada and the United States, but into Great Britain, where, to judge by the testimony of eminent flock-masters, it is held in high esteem. We believe it to be a thoroughly efficacious, and with ordinary precaution a perfectly safe application, and have no hesitation in commending it to the attention of Canadian farmers.

Horticulture.

EDITOR—D. W. BEADLE,

CORRESPONDING MEMBER OF THE ROYAL HORTICULTURAL SOCIETY, ENGLAND.

Fruit-growers' Association of Ontario

The regular winter meeting of this association was held on the 3rd of February, 1870, at the Court House, in the city of Hamilton. There was a very good attendance of members, and considerable interest manifested in the subjects discussed.

The meeting was called to order by the President, Rev. R. Boraet, and after reading of minutes,

Mr. Rykert called attention to the Fruit Prize List of the Agricultural and Arts Association, and suggested the desirability of having it extended and better classified.

Mr. Mills stated that he had no doubt the Agricultural Association would alter the prize list to meet the views of this Society, as they had made many changes last year upon his recommendation.

This subject was left in the hands of the President, and the meeting proceeded to the discussion of the first subject,

THE PEAR BLIGHT.

Mr. A. P. Farrell, of Cayuga, had tried iron filings, applied to the roots by mixing them with the soil, and at the same time carefully and thoroughly cut out the blighted and affected portions of the trees, and they had grown very thriftily since.

Mr. Bennett, of Brantford, had tried the same application and treatment, and thought he had found it to be very beneficial until this year, when very many of his trees blighted, and there seemed to be nothing left but to cut off the diseased portions as often as they appeared.

Mr. Arnold, of Paris, was entirely at a loss what to say or do concerning this disease. It had baffled all his skill, and set at nought all his attempts to devise a remedy, and he had none to offer.

Mr. Morse, of Smithville, had but little experience with the pear blight. (Fortunate man.) It was only when trees made a very luxuriant growth that he had found them liable to be killed back, probably by the effects of the winter. He mentioned an experiment that had been tried by some gentleman, who gave some of his trees very high cultivation, and some very little care. Those that were highly cultivated were all of them more or less affected, while those with but little cultivation were all good and sound. He was inclined to believe that the trees suffered most from sudden changes from heat to cold in the early part of the growing season. He thought that the application of ashes, and perhaps, of a little lime, was of the greatest possible benefit in the culture of the pear, both as regards the blight and the general growth and vigour of the tree.

Mr. W. H. Mills, of Hamilton, thought there were three causes of blight in the pear tree: First, frozen sap blight; second, summer blight, arising from different causes, and third, a blight caused by fungoid growth. He thought that if evaporation is rapid during the growing season, and the tree is not well supplied, and this condition is followed by a few days of warm rain with a close atmosphere, then the tree becomes gorged with sap, the overstrained sap-vessels burst, turn black, and are in a fit state to be attacked by some fungus, which finds in this condition of things just that which is most conducive to its own rapid growth.

Judge Logie, of Hamilton, had applied coal ashes, mixed with wood ashes and a little well rotted manure, and has neve known the trees thus treated to become blighted. He thought the soil had much to do with the blight, and that in soils in which lime is deficient, the application of a moderate quantity was highly beneficial.

Mr. A. M. Smith, of Lockport, N.Y., said he had much faith in the use of lime and wood ashes. He also washes his trees with soap and lime-water, and does not cultivate very highly.

Mr. Holton had watched with much interest the progress of a pear orchard belonging to Mr. Lewis Springer, who had made an incision into the bark of the trees, running from the limbs down the trunk to the ground. This cut was made just through the outer bark, but not down to the wood, in the month of June. Thus far, this orchard had escaped the blight. He has also been seriously troubled with a blight in his crab apple trees, especially in the Montreal Beauty, which is not a very rapid grower, and thought the disease to be the same as the pear blight. It usually began in the tops of the trees, and worked downward.

Mr. Arnold asked if any one had seen a pear tree blighted, the cultivation of which had been wholly neglected.

Mr. Rykert replied that he knew of an orchard of dwarf pear trees in the vicinity of St. Catharines which had been totally neglected, was allowed to grow up with weeds and grass that nearly hid the trees from sight, and a large part of that orchard had been killed with blight.

Mr. Mills said he had for several years past been in the habit of making longitudinal incisions in the bark of his pear trees, in the manner mentioned by Mr. Holton, and had not found any of his trees to be affected with the blight since he had tried this plan.

Mr. Saunders, of London, stated that he had an orchard of pear trees in a light, hungry soil, and one of those trees was killed by the blight. That one had made the least growth of any.

Mr. Bennett remarked that the frozen sap blight which appeared in trees making too rapid growth was easily understood, but the other blight, which he thinks is quite distinct, known as the fire-blight, is a puzzle.

Dr. L. Cross, of St. Catharines, has noticed a form of blight which is indicated by the bark turning black in spots, and that the trees which are attacked in this way *always* die

Mr. Freed, of Hamilton, thought that the blight was more prevalent after a severe winter. He was disposed to believe that the severe frost was the first cause of the blight, the hot summer finishing the evil then commenced.

Mr. Beadle thought there was only one disease, which was varied in its manifestations, and that it was well known by the name of fire blight. He had seen this disease in seedling pear trees that had never passed through a winter, and known them killed entirely by it. He had known charcoal used, and for a time it seemed to have the effect of preventing the blight, none having been seen among the trees so treated for some eight or ten years. But all at once the blight broke out again, and many of those trees were killed by it. He had seen trees growing in clay soils, in sandy soils, and in gravelly soils, alike suffer from this fire blight, had seen them blighted when growing wholly neglected in a fence corner, as well as when carefully cultivated in the garden. He trusted, however, that further and protracted experiments would be tried, in hopes of yet finding some remedy or preventive of this disease.

On motion of Mr. Morse, seconded by Mr. Rykert, leave was granted to introdnce at this meeting a memorial to Parliament, in effect praying that our Government would impose upon fruit trees coming into Canada from the United States the same duty that is imposed by that Government upon the same articles, when sent there from Canada.

The meeting then took a recess until two o'clock p.m.

AFTERNOON SESSION.

Messrs. Holton, George Leslie, jr., and C. Arnold, were appointed a committee to examine and report upon the seedling apples and other fruits on the table.

There was a very fine collection of many varieties of winter apples and late keeping pears on the table, brought together by the members from different parts of the country.

The reports of the Society for the year 1869 were distributed to the members present. Members entitled to them who were not present will receive them by mail.

Mr. Morse introduced the memorial to the Legislature, stating that he was a free trade man, and felt that if our Government would impose upon the products of the United States the same duties that they impose upon our products, they would soon see the folly of attempting to drive us into annexation by the course they were now pursuing, and would be very glad to return to a more liberal policy.

Considerable diversity of opinion was expressed, and an animated discussion was maintained for some time, which we omit, as throwing no light on the cultivation of fruits.

It was at length resolved, by a vote of seventeen to ten, to send the memorial introduced by Mr. Morse to the several branches of the Legislature, and that the President and Secretary sign the same.

Nothing new was elicited on the subject of winter pears. The President spoke very highly of the Beurre Millet, had found it a very fine pear, and thought it well worthy of trial.

The Beurre Millet, of Angers, is a very vigorous and productive tree. The fruit is of medium size, having a greenish skin, covered with russet, and thickly sprinkled with minute russet dots. The flesh is whitish, somewhat buttery, juicy, melting, with a brisk vinous flavour. In use in December and January.

SUMMER PINCHING

was the next subject discussed.

The President stated that for eight or nine years he had pursued the system of pinching in the growing shoots. This should be done in dry weather, and on no account is it to be done in wet weather. The effect of this summer pinching was to increase the quantity of fruit, and induce the trees to fruit earlier. This pinching should be done in the end of June or beginning of July.

Mr. Townsend, of Hamilton, said he had a large number of pear trees under his care, always summer pinched in the manner described by the President, and was fully satisfied of its beneficial effects.

Mr. Saunders agreed in the main with the President, but had found that you could not always depend upon obtaining greater fruitfulness by summer pinching. He had a plum tree which he had summer pinched most thoroughly, in the hope of making it fruit, but it had spent its whole force in making wood, in despite of all his pinching.

Mr. Beadle was of opinion that the tendency of summer pinching was to arrest the wood growth and induce the tree to form fruit spurs. There may be occasional exceptions, owing to some peculiar counteracting cause, but in the main the effect may be relied upon.

THINNING OUT THE FRUIT.

Mr. Morden, of Halloway, county of Hastings, thought there could be no question but that the thinning out of the fruit was very beneficial both to the development and perfection of the fruit that was allowed to remain, and to the tree.

Mr. Mills had had considerable experience in thinning out the fruit, and found it to be exceedingly beneficial. He instanced a dwarf apple tree, of the variety known as the Alexander. He commenced to thin this out when the fruit was quite young, about the size of a walnut, and removed about half of the fruit. Later in the season he became satisfied that he had left too much fruit on this tree, and he thinned it out again, and finally left about half a bushel on the tree, and as the result of this thinning, every apple was perfect, they were of uniform size, and perfect beauties. He takes off the smaller and imperfect fruit, and is confident that the value of the crop thus obtained is decidedly greater than if the entire crop set were allowed to remain on the tree.

Mr. Morse and Mr. Freed confirmed what had been said, believing that both size and quality of the fruit were improved by proper thinning out, and that the price realized from the fruit of an orchard would be greater than if the whole were allowed to grow.

The President stated that if only the proper quantity of fruit were allowed to grow, which of course varied with the size and vigour of the tree, plenty of fruit spurs would be formed by the tree for the production of fruit the following year; but if all the fruit was allowed to grow and ripen, the tree would not form fruit buds for the next year, so that there would be always fruit only every other year. By judicious thinning a crop of fruit is secured every year.

Mr. Beadle believed from actual experience that it would pay to hire a good hand at a dollar and a quarter per day to go carefully through the orchard, and thin out the fruit from those trees that had set too much.

KEEPING FRUIT.

Mr. Mills said that while in attendance upon the American Pomological Society at Philadelphia, he saw fruit that had been kept for a year in a fruit house, without change or deterioration, and thought it was very desirable to adopt such a plan. He kept his own fruit in an ordinary cellar lined with water-lime.

Mr. Saunders said that it would be very easy to try the experiment of keeping fruit in an atmosphere of carbonic acid gas, which prevents the action of the air upon the fruit, and suggested that members make the trial.

Mr. Bauer, of Hamilton, said that he had kept currants and grapes in cans charged with sulphurous acid gas, if put in a cool place. He had tried to keep them in this way in a warm place and had failed. This gas had no effect on the flavour. He had kept cherries nicely until Christmas, and should experiment further.

Mr. Saunders had tried sulphate of soda, but found it to give a strong nutty flavour, which was not satisfactory. Carbonic acid gas, on account of its great specific gravity, was very easily tried. Sulphurous acid gas escaped easily.

Dr. Cross said that sulphurous acid gas absorbed oxygen from the fruit, and kept it in a fresh state without fermentation or decay, while carbonic acid gas only excludes the oxygen of the atmosphere.

The President said he would recommend to pack fruit in nice, clean, washed sand. It would keep plums and cherries for a considerable time beyond their natural period of ripening. A cold room of even temperature would keep fruit much longer than one where the temperature was constantly varying. Pears placed in a close drawer kept in perfectly good condition for a month or six weeks longer than those exposed in the open air of the room. Pears tied up in paper bags keep much longer and ripen better than if exposed to the air.

Mr. Mills said he put some Belle Lucrative pears in clean washed sand. They kept for three weeks after the others were ripe, and were then not ripe, but on being taken upstairs ripened in a few days, but lost their flavour.

Mr. Hatt, of Dundas, headed up tightly in a barrel some snow apples, and kept them in a cold cellar, almost at freezing point, and they turned out exceedingly well.

SHIPPING FRUIT.

Mr. Ball, of Niagara, said that any clean-looking, well flavoured apple, can be shipped if properly packed. The chief point was the packing. He had shipped with sweating and without. Only first class apples should be used. Each basketful of apples, when put into the barrel, should be carefully shaken down, and the barrels filled nearly even with the top, the heads put on and pressed to their places. He had shipped several varieties—Russets, Ribston Pippins, etc. Apples required to be of good flavour and colour to sell well in Europe, and to be of uniform size, never more than two sizes in the same barrel. He did not think it advisable to press more than an inch and a half.

Mr. Mills described Mr. Springer's mode of packing apples. He does not shake them down as he puts them into the barrel, but after he has filled the barrel he puts on a cone of inferior apples to receive the crushing and then presses them down. Mr. Springer is very successful.

Mr. Keating thought that when the apples had to be transported over rough roads it was necessary to press more than when they need to be taken only a short distance in waggons or over smooth roads. He is in the habit of pressing the fruit down about three inches. Only the top ones are bruised.

Mr. Ball recommended that each shipper should put his name and mark on each barrel of apples he sends out. In this way the fruit and shipper become known and obtain a character in the market, and a price suited to its character. He also remarked that the Green Newtown Pippin sold for the highest price in England, and if it could be grown clean and free from spots on a favourable soil would be a profitable variety to ship to Europe.

Mr. Beadle said it was an utter waste of time and money to attempt to grow the Green Newtown Pippin for shipping from this country. It does not grow anywhere in this country in good order with certainty; it spots badly, and the tree fruits sparingly. It will not pay to grow it.

Mr. O. Hammond said he grew it in good order, but it did not bear so well as other varieties.

A resolution was passed recommending to all growers of fruit to mark their packages with their names, or some distinctive mark, by which they shall be known readily in the market.

Some discussion was had as to the time of holding the summer meeting, and the opinion of the meeting seemed to be that the best time would be when the Raspberries were ripe.

The subject of holding an autumn exhibition of fruit was laid over for consideration at the next meeting.

It was requested that the "Pruning of Fruit Trees" might be discussed at the summer meeting.

The committee appointed to examine the new seedling apples and other fruits on the table made their report, and the Association adjourned, to meet in London at the call of the President.

REPORT OF THE COMMITTEE ON SEEDLING APPLES AND OTHER FRUITS.

Seedling apples shown:—

Mr. James Best, Toronto, a pretty medium sized red cheeked apple, much resembling the Wagner, but inferior to it in flavour.

W. J. Marsh, Clarksburg, two seedling apples, both past their season, one resembling the Holland Pippin, but not equal to it; and one resembling the Rambo in appearance, but earlier, and not having, in our opinion, any distinctive merits.

W. E. Coleman, Lyn, two seedlings, one a small to medium apple, mild flavour, no merit; the other a very large, exceedingly showy, red apple, very much dotted, rather over ripe, evidently a late Fall apple, flavour mild sub-acid; worthy of trial.

Mr. Atwood, London, shows an apple of large size, supposed to be a seedling, in flavour and appearance very much resembling the Ribston Pippin; if proved to be a seedling of Canadian growth, we consider it to be the best that has been brought before our notice.

D. Hammond, Toronto township, one seedling apple, conical, with a red cheek, handsome, flesh almost white, rather coarse, mild flavour, core large; worthy of trial; also one called Andrews' Russet, a flattish medium sized russet, with a very red cheek, flesh white and of good flavour, specimens rather past their season.

E. R. Morden, two seedlings, small fruit, both past their season.

In apples of cultivated varieties, the display was very large and fine. Amongst the best, we note Swayze Pomme Grise, Cayuga Redstreak, King of Tompkins County, Melon, Swaar, Wagner, Northern Spy, and Lady Apple.

The display of pears, comprising some twenty kinds, was, for the season, very good, but many kinds were past their season, and nearly devoid of flavour. Well preserved specimens of Beurre Diel, Beurre d'Anjou, Vicar of Winkfield, Duchesse d'Angouleme, Winter Nelis and Verte Longue, were noted.

Mr. Cross, Oakville, exhibited samples of a strawberry basket that seemed to your committee to combine cheapness with durability to a very desirable degree.

CHAS. ARNOLD.
W. HOLTON.
GEO. LESLIE, Jr.

MEETING OF DIRECTORS.

A meeting of the Directors of the Fruit Growers' Association was held in the Court House, Hamilton, on the evening of the 3rd of February, 1870.

After the transaction of some routine business, the Secretary laid before the Board the three essays which he had received in competition for the prizes offered by the Association, and the Board appointed the President, Mr. Mills and Mr. Holton a committee to read the essays and award the prizes.

After hearing Mr. Freed's report on some crab apples—

A resolution was passed, thanking Mr. Cowherd, of Newport, for his exertions in producing superior varieties of the crab apple.

Mr. Rykert gave notice that he should, at the next meeting of the Directors, move a resolution that a Fruit Show be held by this Association in the fall.

The auditors' report was read, and the Secretary instructed to obtain sufficient vines of the Rumelan grape to give one to each member, and to each person who shall become a member before the first day of April, 1870, and who notifies the Secretary of his willingness to make the report thereon required by the Association.

Adjourned to the call of the President.

REPORT ON CRABS.

I examined and tasted the two varieties of fruit left at my place for my opinion, and beg to say:

No. 1, from Sarnia, is of very fair size for a crab, and although past its best, I would say it is a desirable fruit for a crab, particularly on account of its good keeping qualities.

No. 2, from Brantford (Mr. Cowherd's variety) is a very handsome fruit, of medium size, and very pleasant flavour, losing all the harsh and austere flavour of the crab, for the higher and finer flavour of our best apples approaching very near to the Scarlet Pearmain, which is a very good early dessert fruit.

To call it a crab, I think, surely, is a misnomer, and one that I think should engage the attention of the Society for a more suitable definition.

And here I would beg to remark that I know nothing of its parentage, but understood it to be a cross effected by Mr. Cowherd. This success of Mr. Cowherd in breaking down the harshness of the crab for the better qualities of the apple deserves encouragement, and a special vote of thanks by the Directors of the Association.

And I trust the Directors will offer good inducements for the best six or any other number of cross seedlings, raised from our best varieties of crabs and Russian varieties of apples, in the hope of raising hardy fruits of good size, and suitable for cooking and dessert. Fruit that can be raised in our far northern counties, of good second quality only, would confer a great boon on them, and one which I think the Association should keep in view.

JOHN FREED.

P.S.—My remarks are meant to apply to our northern counties for the fruit in question, thinking that in our more favoured locality more crabs are not required.

J. F.

Hamilton, December 29, 1869.

Meeting of Grape Growers

The grape growers of Western New York ave recently held their annual meeting. The writer was not able to attend, but from the reports, it seems to have been an occasion of much interest.

A long and animated discussion was held on the vexed question of pruning. Some advocated a partial pruning in the fall or winter, leaving a superabundance of wood, and then a second pruning in the spring or early summer, after the new growth has reached four or five feet in length. At this second pruning the new growth is not shortened in, but the entire shoot, leaves, fruit and all, cut away. The amount of pruning is regulated by the apparent strength of the vine.

This plan seems to us to entail an entirely unnecessary amount of labour, compelling the cultivator to go over his vineyard twice to accomplish what may as well be done at once. The reason given for only a partial winter or fall pruning was that the fruit sets better for leaving plenty of wood. This is true. But why does the fruit set better for leaving plenty of wood? It is because close fall or winter pruning causes the vine to suffer so severely in an intensely cold winter that the buds are injured, their vitality weakened, and, consequently, the fruit cannot set. The true and most economical method is not to prune in the fall or winter in this climate at all, but to prune between the 15th of March and the 15th of April in most seasons, and do all the pruning for the whole season at that time. Great objection has been made by some theorists to this spring pruning, on the ground that the vine weeps or bleeds at the cut, if made at this time, and that this weeping or bleeding was injurious to the vine. But this supposed injury is all a theory, After some years of trial of spring pruning, we have become perfectly satisfied that it is the very best season for pruning the vine, and that the weeping of the sap from the wounds is not in the least injurious. The plan pursued by the President (Mr. Pottle) is an approach to that of spring pruning. He prunes *lightly* in the fall or winter, and when it is apparent that the wood has wintered well, prunes again. If too much fruit sets, that he thins by removing the whole shoot on which it is. Some fruit may be removed from the shoots that are left, but the shoot is not shortened.

Several of the gentlemen present testified to the fact that the weeping or bleeding of the vine from spring pruning did not produce any bad effects, and many were fully persuaded that close planting and summer pruning were very injurious.

These are symptoms of progress, and in time the vine cultivators of America will learn the distance best suited to our varieties of the grape, that our vines will not bear fall or early winter pruning in this latitude, and that it is worse than a waste of time to cut away the leaves in summer.

An experiment was described by the President which ought to satisfy the most sceptical, and which fully proves that the grape does not need light upon the fruit in order to ripen. A gentleman enclosed a bunch while the fruit was of the size of buckshot, and quite green, so as to be in complete darkness, and it ripened and coloured perfectly. Ye advocates for summer defoliation, for cutting off the leaves so as to let the sunlight in upon the fruit, what excuse have you now for your harmful practice? Did you ever see a wild grape vine that had covered some tree top, and count its purple clusters hanging in the deepest shade, where no straggling sunbeam ever had leave to enter? And did you never notice, after your summer's leaf stripping, that the fruit you expose to the full glare of the sun never would colour perfectly, no, nor ripen perfectly either?

It was also brought out in these discussions that the base bud, and sometimes buds, will not produce fruit, and that observing vine-dressers are depending for fruit upon the third and fourth buds.

The President cautioned the members against deep ploughing in the vineyard, and advised the use of the cultivator in its stead. He stated that it was very important to the early ripening of the fruit that there should be plenty of surface roots; that deep-rooted vines ripen their fruit late, if at all.

On the subject of varieties there was great diversity of opinion. Some esteemed the Concord very highly for profit, One said he got more pounds per vine from the Delaware than the Concord. It would seem that the Iona cannot be depended on where the Catawba does not ripen, though it was admitted to be a little earlier. Several spoke very highly of the Eumelan, and no one had anything to say against it.

The Eumelan is the variety which the Fruit Growers' Association of Ontario is distributing to its members, on condition of receiving an annual report for five years of its behaviour, and in a few years more it will have been fully tested in this Province. Any one becoming a member before April 1st can have a vine if he wishes, by sending his name and member's fee to the Secretary, Mr. D. W. Beadle, St. Catharines.

Report of the Fruit Growers' Association for the year 1869.

This report, covering seventy-two pages, is full of information relating to the cultivation of fruit of different kinds in the Province of Ontario. It contains the Directors' report, the Treasurer's report for the year ending 21st September, 1869, the Officers for the present year, the address of the retiring President, W. H. Mills, Esq., delivered at the annual meeting, and full reports of the discussions on different varieties of fruits and their cultivation, which were had at the three general meetings held since the last report, one of which was held in St. Catherines, another in Hamilton, and the third in Galt. There is also a very complete synopsis of the returns made from all parts of the Province to the questions which were issued by the Commissioner of Agriculture at the request of the Fruit Growers' Association. This synopsis is divided into nine heads, thus bringing together as nearly as possible the returns from those parts of the Province which are most nearly alike in their climate. These divisions are designated as the Ottawa, St. Lawrence, Ontario East, Ontario West, Niagara, Erie, Huron, and Internal Divisions, and the District of Algoma.

It also contains an essay on the culture of the apple, an article on the cultivation of the pear, a paper on the plum tree, another on the culture of the currant, several short articles on the grape, one on the raspberry in 1867, and other fruit reports. It should be in the hands of every grower of fruits in Ontario, and will be sent to every one who now is a member of the Fruit Growers' Association, and to any person who sends his name to the Secretary, Mr. D. W. Beadle, St. Catharines, together with one dollar, requesting to be enrolled as a member of the Association.

Does Nature Economize her Forces?

To the Editor.

SIR,—I do think, after all, the really valuable lessons to be learnt in horticulture are those obtained by a close observation of the laws which govern vegetable development and by a strict adherence to them. There are too many who turn the index finger in a wrong direction, and then pursue the course with a tenacity worthy of a better cause.

I scarcely know why I take my pen to address you, unless it is through the hope that the few remarks I have to make may fall, by means of your widely circulated paper, under the notice of parties deeply interested in the production and dissemination of new cereals and plants in our Province. It seems to me the too great haste to make rich often compels us to pursue with the greatest tenacity an idea (false in itself) until it becomes so thoroughly grounded in the individual mind, that the oft-recurring thought seems like truth at last, and by such process becomes conscientiously foisted into public literature,

and thereafter such error requires to be worked out by a tedious public experience.

Many experiments recently made go to prove that not only roots, but fruits and grains, when grown at greater than usual distances apart, will yield larger crops and give greater returns than we had any previous conception of. It was shown to be the case in the yield of the grape vine, satisfactorily established, I think, by Mr. E. F. Underhill, in the November number of the *Journal of Horticulture*, page 257. It has also been shown to be the case both in potatoes and corn, and recently with wheat. Mr. Charles Arnold states that in the course of his experiments in hybridizing this cereal, he obtained from one kernel the astonishing number of 4,800 kernels; and in the subsequent year, 1869, the same variety yielded seventeen bushels two quarts and one pint, from seven pounds of seed—a result which, however wonderful, is altogether out of proportion with the enormous product of the first single berry. The contrast will be better understood by taking each bushel as weighing sixty pounds. We have then 1,026 lbs. as the yield from seven pounds. Therefore, as one grain is to 4,800, so is seven pounds to 1,026 pounds. This result must have been produced from the space of ground occupied by each grain. There was nothing to interfere with the first grain's productiveness; there was no struggle for life against similar competitors; but in the planting for 1869 it was quite otherwise. I cannot, therefore, avoid the conviction that in case the same variety be planted as in ordinary culture, a relative minimum of productiveness will be attained.

It is found that the wheat plant increases in proportion as its roots have room to develope, without interference with those of its neighbours. I am unable just now to lay my hands on an experiment which went to prove when room was given for the development of the root, that the wheat furnished ears containing over 120 grains, and by the same experiment it came to pass, that on every fully developed cereal plant there was always one ear superior to the rest, and, what was still most remarkable of all, each ear contained one grain which, when planted, was more productive than its fellows. Now, here the finger of nature's index points pretty clear. Select the best grain from the best ear, and quietly continue this for a few generations, and it will certainly bring you to a point of glorious perfection. If this becomes a recognized law, its application may be made in various products. And to attain the grandest results from the works sent forth from the Creator, nature often presents numerous and auxiliary ways to the same final purpose, and the mind which embraces the widest range of these auxiliary aids, wins the race.

To make a further analysis of Mr. Arnold's wheat experiment, it will be observed that one single kernel produced 4,800 kernels. To do this it must have equalled forty footstalks, or have been double-headed (which could scarcely have been the case), each footstalk containing one ear with the enormous number of one hundred and twenty kernels or grains each; this, it must be admitted, was a wonderful yield of the germ force. But such results may only be obtained, if ever, when planting takes place so that the roots may in no wise interfere and rob each other of that particular pabulum which goes to form the future germ or seed. I have frequently witnessed the ill effects of overcrowded planting in its non-productive results. It is thus clearly indicated that our trees and vines should be planted far apart. Avarice often defeats the very ends we wish to accomplish, and so we plant thick, hoping to double our profits.

I had the pleasure of witnessing a single Isabella grape vine this last season occupying a space of fifty feet long by eight feet high, with such an enormous load of fruit, that I can safely say that no other six vines of the same species could have been made to produce such a quantity on the same space. I am compelled to come to the conclusion that nature does economize her forces, when she can be made to produce from a single vine in a given space, as much as, or even more fruit than six vines occupying an equal space; or when a single grain may be made to produce more than forty grains improperly sown.

W. H. MILLS.

Hamilton, January 19, 1870.

On the Hybridizing of Pelargoniums.

The practice of impregnating flowers in order to produce varieties has of late been extensively adopted by gardeners and planters; but the proceeding is rarely, if ever philosophically investigated. Impregnation is effected by contact between the pollen and the stigma. The pollen is the farina or dust which escapes from the anthers of a flower when its valves burst open. The stigma is the point or termination of the pistil, which secretes a viscid juice. Whether the stigma be furnished with such juice or with a velvety pubescence, or whatever be the nature of its peculiarly appropriate surface, certain it is, that according to the most accurate observation, this organ is the only portion of a perfect vegetable which is not invested with a cuticle or epidermis.

The pollen emits a tube of extreme delicacy, which pierces the stigma, and still passing downwards into the ovary, enters the foramen of the ovule. So much has been written and published on cross-breeding, that it would be next to impossible to advance any theory respecting it, yet a few hints on the practical part of the work may not be out place, but might induce some to try their hand at this very interesting work, who are, perhaps, deterred from doing so, not knowing exactly how or when to apply the pollen, or other little matters connected therewith, so as to gain any satisfactory result.

One of the most important matters in connection with hybridizing, as in almost all undertakings, is to hit upon some kind of definite standard to be attained, so that the operator may have some decided object in view to look forward to and try to gain—in fact, have a decided reason for what he is about to do. By this course, the operator will be far more likely to arrive at some satisfactory result, than by merely trusting to the chance of getting something good just because he may happen to have crossed this variety with that. It is a common but delusive idea, that two varieties, being distinct will be sure, when crossed, to produce something different from either of the originals though it is just a chance if one of the seedlings so produced will be better than the parents, or even equal to them. Presuming, therefore, that the hybridizer is desirous of obtaining some particular cross with the object of arriving at the result he has set before him, and has fixed upon the varieties which he intends using for the purpose, the next important matter is to select good healthy plants as *parents* on both sides, as without healthy parents you can never expect seedlings from them to be strong and of good constitution; even though they be the most beautifully marked and distinct in flower, they can but be counted second rate. Having, then, made choice of good healthy plants of the varieties it is intended to hybridize, all the flowers that are expanded upon the plants that are to be used as seed-bearing parents should be taken off and the plants removed as far from others as possible, or if they can have the house to themselves so much the better; still, if care be used, this is not absolutely necessary. Watch the seed-bearing parents closely every day till the first flower opens, and immediately the petals are sufficiently expanded to admit of its being done without injury to the flowers, perform the first operation. The anthers, which are the male organs, appear as little knob-like portions, standing up prominently in the centre of the flower; these must be carefully taken out, without injury to the centre column or pistil. Always bear in mind that there are, in a perfect geranium flower, also two of the said anthers, lower down the centre of the flower than the rest, which must also be carefully taken out.

This can be done by a pair of sharp pointed scissors, or a penknife. Having satisfactorily accomplished this operation, watch carefully the progress of the female organ of the flower to its maturity, which in healthy flowers takes two or three days from the time the flower expands. Double flowers are an exception to this rule, for I find they take twice as long as the single to come to maturity. Last year I had sixteen seeds from Gloire de Nancy, and Triumph As I am writing this principally for amateurs, I ought, perhaps, to explain here that the female in a pelargonium is the stiff thread-like portion coming immediately from the centre of the flower, and surrounded by the filaments

bearing the anthers and having the appearance, in its earlier stage when the flower first opens, of one single thread-like projection, but which, as it advances to maturity, divides into five distinct parts, at the point, each division being the direct channel to a distinct seed-vessel at its base. Now, it is just this period of arriving at perfection in the female organ that is one of the most important matters in hybridizing. The best time, in my opinion, and what I generally follow in practice, is to apply the pollen as soon as possible after the division of the pistil into its distinct parts takes place, and before it has expanded to its full size. It is not only in its best state then for receiving the pollen, but there is less likelihood of its becoming impregnated with other than that intended. I may add that once impregnated with the one desired, all foreign pollen coming in contact therewith availeth nothing. In selecting flowers choice should be made of the first eight flowers that open on the truss, for as a rule they are the strongest and best. I make it a rule to cut all the others away. And in the choice of plants for a beginning, the following cannot be surpassed, viz: Zonals, White Pefection, Surpass, Beauty de Surennes, Eugene Mazardy, Mme. Warie, Julius Cæsar, Warrior, Criterion, King of Whites, Nosegay, Lady C. Grosvenor, Duchess of Sutherland, Indian Yellow, Dr Hogg, Le Grand, Pink, Stella and Violet Hill Nosegay. Let the beginner procure these few plants, for a start, and when purchasing be sure to get two year old plants.

JAMES J. CRAIG.

Toronto Horticultural Society.

This society held their annual meeting on the 8th of February. The report of the past year gave a very satisfactory account of the position of the Society and the state of its finances, a large portion of the debt having been cancelled, leaving at present only $800 due, which sum, it was hoped, would be raised over and above the expenses during the current year, so as to leave the Society entirely unburdened by any debt whatever. The Horticultural Gardens had undergone several improvements, among them the introduction of a rosery, which promises to thrive, and add a very attractive feature to the grounds.

The officers elected for the ensuing year were as follows:—

President—Hon. G. W. Allen; 1st Vice President—Philip Armstrong; 2nd do. F. W. Coate; Corresponding Secretary—Walter S. Lee; Recording Secretary—Henry Pellatt; Treasurer—James E. Ellis.

Directors—Rev. E. Baldwin, Thos. D. Harris, Geo. Leslie, Senr., J. Gibson, J. C. Gilmour, J. Forsyth, John Gray, Wm Ince, Geo. Leslie, Junr., J. H. Mason, F Sutherland Stayner, S. A. Summers, Jas. Fleming, John Paterson, Geo. Vair.

A resolution was carried affiliating the society with the Fruit Growers' Association.

Orchard Wind-breaks.

To the Editor.

SIR,—I noticed a communication in the December number of the CANADA FARMER, signed "Observer," asking for experience respecting planting trees for wind-breaks to shelter fruit orchards.

I write to give you my experience for the benefit of "Observer" or others that may be interested in planting trees to shelter their orchards.

Six years ago I prepared a strip of ground on the north-west side of my orchard, and set a row the full length of the orchard with the cuttings of Lombardy Poplars, setting them about fifteen inches apart. The result was they grew so rapidly that they astonished not only me but every one who saw them. I kept them well cleaned and cultivated, and cut about two-thirds of the centre shoots every year for four years, to make them branch out near the ground. It now makes a complete wind-break twenty feet high. During the summer and fall it is equal to evergreen trees, as the leaves hang on till the snow falls.

MY MISTAKES.

I made a mistake in setting the cuttings where they were to remain. Some few of the cuttings failed to grow; of course I filled up the spaces by planting more trees, but the others had possession of the soil, and they took the lead, so that I could not fill the breaches effectually. Those spots, though but few, are now an eyesore, and I would give almost any price to remedy them. Another mistake I made was in planting too close to my fruit trees. They should be at least twenty-five feet away; mine are only fifteen. If I were going to plant again I would plant trees two years old from the cutting, and cut them back well. There would not be the danger of their failing that there is when set without roots. The trees should be sorted and planted regularly according to size, beginning with the largest and finishing with the smallest, and those that grow the fastest should be cut back the most. Treated in this way they will make a good fence in six or seven years. Part of mine will now turn anything from a pig four months old to the wildest bull.

I am satisfied that the value of trees planted for shelter, not only to the orchard but to all exposed farms, can hardly be over-estimated. There are doubtless many kinds of trees that are adapted for this purpose. The advantages of the Lombardy Poplar are, first, they can be propagated so rapidly from the cutting that the trees cost less than almost any other kind. Secondly, they will thrive in almost any soil or situation. Thirdly, they will grow so close together that they almost touch each other, and still thrive. And lastly, there is perhaps no tree that will make wind-break in so short a time.

S. H. MITCHELL.

St. Mary's, Ont.

NOTE BY ED.—This communication is just what is wanted. The actual experience, for and against, of one person is worth a thousand-fold the best guessing of the wisest.

Toads vs Bugs.

We make the following extracts from some passages in Fogt'a book, "on Noxious and Beneficial Animals," which are quoted at full length in the fourth number of *Le Naturaliste Canadien*. For the benefit of the American reader, we translate from the original French.

"A remarkable fact has lately been published in the newspapers. There is actually a considerable commerce in toads between France and England. A toad of good size and in fair condition will fetch a shilling (twenty-five cents) in the London market, and a dozen of extra quality are worth one pound sterling (five dollars). You may see these imported toads in all the market gardens where the soil is moist, and the owners of those gardens even prepare shelter for them. Many grave persons have shaken their heads, when they heard of this new whim of the English; but those laugh the best who laugh the last. This time the English are in the right. I used to have in my garden a brown toad as big as my fist. In the evening he would crawl out of his hiding place and travel over a bed in the garden. I kept careful watch over him; but one day an unlucky woman caught sight of him and killed him with a single stroke of her spade, thinking she had done a very fine thing. He had not been dead many weeks before the snails ate up all the mignonette that formerly perfumed everything round that bed.

"Toads become accustomed to man, and do not appear to be incapable of tender sentiments. Everybody has heard the story, which seems borrowed from some old popular legend, of a toad which for thirty years lived under an espalier tree, and came out every evening, when the family was taking supper, to get his share of the meal like the dogs and the cats. The family shed tears on the day when an accident deprived that devoted servant of life. Some of my friends believe that, after having heaped benefits upon a toad, they have obtained from that despised animal evident proofs of gratitude. A certain Capt. Perry has told me that, in travelling through the interior of Sicily, he once found on the road a snake that was just about to devour a toad. He killed the snake, and the toad went his way. Six days afterwards he returned by the same road. All of a sudden something hops along close behind him. It was his toad, who had adopted this mode of expressing his gratitude towards his preserver, and who had positively recognized him. 'But, Captain,' I said to him, 'how could you possibly identify the particular toad whose life you had saved? One toad is as like another toad as one egg is like another egg.' 'That is very true,' replied the Captain, 'but he looked at me with such grateful eyes, that I could not doubt his identity for a moment."—*American Entomologist.*

Diseased Apple Trees.

To the Editor.

SIR,—Early last summer I noticed that one of my apple trees looked quite black in the bark, as if it had been scorched by fire. For a time I paid but little attention to it, till I saw the bark coming off in scales, and some of the branches showing signs of decay, though others were, to all appearance, perfectly healthy, and bore fruit. I thought, at first, the tree had been struck by lightning, as it was the only one affected. I am sorry to say such is not the case now; for I saw several trees showing the same symptoms. The bark turns black as described, in every case, at the fork of the tree first, extending gradually along the branches.

The trees are seven years planted last spring, and have been well taken care of, the land being tilled with root crops, till the spring of 1868, when it was sown with spring wheat and seeded down with clover. The soil is dry loam, and in good heart.

Could you, or some of your numerous readers, enlighten me as to the cause of, and if possible, the remedy for this blight, or whatever it may be?

J. R.

North Oxford.

NOTE BY THE HORT. EDITOR.—It is always very difficult to decide in such a matter as this, and particularly without seeing the trees and their surroundings. Are trees in other orchards in the vicinity similarly affected? Is the bark that turns black exposed to the direct action of the sun's rays? We have seen the upper side of branches that grew out in a northerly and north-easterly direction lose their bark, which died and turned black, and believe that it is in such cases caused by the sun's rays falling nearly perpendicularly upon them; for the bark not thus exposed to the sun retained its vitality. There is a disease known as the "fire blight," but that usually attacks the young shoots, turning them black.

Northern Spy Apple.

To the Editor.

SIR,—My attention has been directed to an article in your journal, over the signature of an "Amateur Fruit Grower," to which is appended a reply by yourself containing a request that I give your readers the benefit of my experience in the cultivation of the Northern Spy Apple, and my opinion of it as a profitable variety.

I have an orchard of 120 apple trees, 70 of the Northern Spy variety about 20 years old, which have been bearing *annually* for 9 or 10 years, and during the past four years have averaged 140 barrels of selected fruit per annum.

My method of cultivation is to top-dress the soil with short manure, either during the latter part of autumn or in winter, as may be most convenient.

As soon as the frost is out, go over the surface with a common harrow, for the purpose of pulverizing, and securing a more even distribution of the manure; follow with a shares harrow, which is so constructed that it will not cut or injure the roots. Going once over and afterwards crossing your work at right angles leaves the soil thoroughly comminuted to a depth of five or six inches.

Subsequent treatment consists in a repetition of the harrowing when weeds promise to become troublesome or the soil becomes compact.

On the subject of pruning I may remark that the Northern Spy tree requires careful management. The usual cut and slash system will not do; if adopted and adhered to, a rampant growth of long, straggling limbs may result, but fruit will be scarce, and in all probability inferior in quality. Thin the top by cutting out all middle branches, that the tree may acquire a spreading habit, and the sun's rays have a chance to penetrate freely.

Carefully husband all fruit spurs, whether found on the sides of large limbs or smaller ones; many of the best specimens of fruit grow on spurs of six inches or more in length, that may be found projecting from limbs four or five inches in diameter. Doubtless many of your readers will say all this involves considerable trouble. By way of encouragement to others to do likewise, I will state that the net profit on fruit sold from my 70 trees of Northern Spy last autumn amounted to the sum of $560, an average of $8 per tree.

Results similar to the above have so far established this apple, in my opinion as profitable to the fruit grower, that of an orchard of 40 acres, I have planted 800 trees of this variety.

O. T. SPRINGER.

Wellington Square, Jan. 19th, 1870.

When Apple Trees Bear Fruit.

A subscriber writes from Simcoe to enquire when his young apple trees will bear fruit. He says that within the past three years he has planted 700 apple trees of different kinds, which were from three to five years old when he planted them.

As a usual thing, apple trees begin to show fruit, if they are well cared for, by the time they have been five years planted in the orchard. The Red Astrachan, and Duchess of Oldenburgh begin to bear younger than most varieties, then the Ribston Pippin, Early Harvest and Hawley show fruit, but the Northern Spy waits until it has attained considerable size and age before it yields much fruit. The Baldwin, American Golden Russet, Roxbury Russet, and King of Tompkins County will yield considerable fruit when they have been planted seven years. But the profit of an apple orchard depends on the care bestowed upon it. If the insects are allowed to devour it, or the cattle to browse it, or the water to stand about the trees, or pruning neglected, the fruit will not pay for the investment.

Fruit-growing in the County of Kent.

On a recent visit to this county we had an opportunity of making enquiries into the state of fruit culture, and find that the inhabitants are fast becoming convinced that the growing of fruit is one of the most profitable modes of husbandry. Those who have orchards in bearing find that the cash returns from an acre or two will often exceed that of all the rest of the farm. The climate of this county is very favourable for the raising of all the finer fruits of this latitude. The peach, the quince and the grape, on suitable soils, are here grown in perfection. We say on suitable soils, for while the country about Chatham is very flat and poorly drained, and, in consequence, very poorly suited to the profitable cultivation of fruit, yet the southerly portion of the county is broken by a fine ridge, upon which the trees and vines thrive in perfection.

The writer was informed that within a few years a great many thousand fruit trees had been planted, and a large quantity of vines of different varieties of grapes. It was estimated that the aggregate number of acres planted with grape vines would not be short of three hundred. These, if properly cared for, will soon be in bearing, and the quality of the fruit, and its value for market and for wine, will soon be ascertained. We have every confidence that they will be found to be of very fine quality, and well suited to every purpose to which this beautiful and delicious fruit can, in this climate, be applied. It is very gratifying to learn that so much attention is being paid to the raising of fruit, and we trust the day is not far distant when good fruit will be so abundant as to be within the reach of the masses in all our larger towns and cities, and that this wholesome, nutritious and agreeable food will be consumed in double and treble quantities.

The Fruit Growers' Association has a goodly number of members in the County of Kent, and we hope they will invite the Society to hold one of its summer meetings within their borders.

KEEPING PEARS.—The President of the Fruit Growers' Association of Ontario says that those who have but a few pears of a sort will find it very convenient just to place those of each kind in a paper bag and tie it up. They can then be laid upon shelves in a cool room, free from frost, and will be kept without shrivelling or losing their natural flavour.

DAVISON'S THORNLESS BLACK-CAP RASPBERRY.—The *Horticulturist* for December, 1869, speaks in high terms of this variety of raspberry, as being both early and profitable. It has been found to be exceedingly vigorous, quite productive, from seven to ten days earlier than the Doolittle, very large, and fine sweet taste. It succeeds best in moderately rich loams, growing weak on light soil or in a heavy wet bottom.

TOMATOES may be made to ripen early by sowing the seed in March, in a box of very rich soil kept in the kitchen window. After the plants come up, they should be thinned out to about an inch apart. When all danger of frost is past, plant them out in *moderately* rich soil. If the soil be very rich and the season moist, they will grow too much to vines. After a cluster or two of fruit has set upon each branch, pinch it back to the leaf just above the fruit, and keep it pinched back. This will hasten the development and maturity of the fruit. A later sowing will furnish plants for a succession.

SENECA RASPBERRIES.—A subscriber enquires whether the Seneca Black-cap raspberry is a good hardy berry for field culture, and where he can get a lot of plants, and also wishes to know if there is any more profitable berry for raising for the market. The Davidson's Thornless and Mammoth Cluster are both better sorts than the Seneca, and are hardy and prodnctive. In some markets the red raspberries sell better than the black. You should ascertain which sell best at the place where you propose to market the crop. The plants can, no doubt, be had of all our nurserymen. See our advertising columns for names of most of our leading nurserymen.

CRANBERRY CULTURE.—A correspondent at Owen Sonnd asks whether the cranberry should be raised from seed or from runners. The easiest plan for him to adopt will be to procure a quantity of plants from some of the cranberry marshes. If there are none in his vicinity, any of our nurserymen could put him in the way of getting them. They could no doubt be raised from seed, but it would be a much slower process. Under favourable circumstances, the cultivation of cranberries is very profitable. There is an article on their culture in the first volume of the CANADA FARMER, page 106, which would well repay the trouble of perusal. If our correspondent does not happen to possess a copy of the first volume, he can be supplied from this office, either with the volume or with the number for April 15th, containing the article referred to.

PRUNING DWARF APPLE TREES.—"Farmer" asks "When is the best time of the year to trim or prune dwarf apple or pear trees, spring or fall, and why?" In this climate, the best time for pruning apple, pear, and all other trees, is in the spring or early summer, according to the object for which the pruning is done. The reason why is this: the intense cold of our winters acts unfavourably upon a wound or fresh cut made in the fall, often causing the death of the branch so cut, if not wholly at least in part, so that the wound does not heal over at all, or so slowly that the wounded spot is always unsound. If limbs are cut off in June, when the tree is growing vigorously, provided there be not too many cut off, so as to check its growth, the wound will heal the soonest. But it does not follow that therefore it is best always to prune in June.

Poetry.

The Stream that Hurries By.

The stream that hurries by on yon fixed shore
Returns no more;
The wind that dries at morn yon dewy lawn
Breathes, and is gone;
Those withered flowers to summer's ripening glow
No more shall blow;
Those fallen leaves that strew yon garden bed
For aye are dead.

Of laugh, of jest, of mirth, of pleasure past,
Nothing shall last;
On shore, on sea, on hill, on vale, on plain,
Nought shall remain;
Of all for which poor mortals vainly mourn,
Nought shall return;
Life hath his hour in heaven and earth beneath,
And so hath Death.

For all spring gives, and winter takes away,
We grieve in vain;
Vainly for sunshine fled, and joys gone by,
We heave the sigh;
On, ever on, with unexhausted breath,
Time hastes to death;
Even with each word we speak, a moment flies,
Is born, and dies.

If thus, through lesser Nature's empire wide,
Nothing abide—
If wind, and wave, and leaf, and sun, and flower,
Have each their hour;
He walks on ice whose dallying spirit clings
To earthly things;
And he alone is wise whose well-taught love
Is fixed above.

Three Roses.

Which is the happiest rose to-day,
Of the three that I know, I wonder—
The rose in the window, the rose on the lawn,
Or the rose in the meadow yonder?

Fair as a pearl is the face of one,
While it dewily gleams and flutters
Close where its peaceful heart can hear
What the peaceful household utters.

Velvet petaled and crimson lined,
With mosses its stem enfolding,
One burns up from the flattered lawn,
A marvel to all beholding.

And one on the barren meadow lives,
Near a boulder huge and sullen;
A pale, wild thing in a lonely world
Of thistle and weed and mullein.

Happy those treasured garden blooms,
In their white and crimson graces.
But she of the meadow is happiest,
Who looks but to God for praises!

Departed Days.

Oh, memories of green and pleasant places,
Where happy birds their wood-notes twittered low!
Oh, love that lit the dear familiar faces
We buried long ago!

From barren heights their sweetness we remember—
And backward gaze with wistful, yearning eyes,
As hearts regret, 'mid snow drifts of December,
The summer's sunny skies.

Glad hours that seemed their rainbow tints to borrow
From some illumined page of fairy lore,
Bright days that never lacked a bright to-morrow;
Days that return no more.

Household.

Catching Rats

Every one has found the difficulty of inducing these vermin to enter a trap, especially after one has been caught. Rat catchers say that the rats smell the iron, and at once dread difficulty and danger. I have been much troubled in our house by rats lately, and all attempts to catch them with ordinary means failed.

A friend with whom I was conversing on the subject, and to whom I stated my difficulties, told me to set the gin in the ordinary manner, and to cover it over by spreading a piece of thin wet paper on it. I did so, and placed some bread crumbs on the paper, and now find no difficulty in catching the rats. It seems they cannot smell the iron through the wet paper, which being softened offers no resistance to the action of the trap, and an excellent medium is thus obtained on which the rats will freely tread as being accustomed to, and death is the result. C.

How to Clean Old and Musty Barrels.

At this season of the year the farmer and beef and pork packers are often greatly troubled with musty, filthy smelling barrels, bottles, etc. How to cleanse them for use is an important question, which chemistry will answer satisfactorily.

Permanganate of potassa will entirely destroy all fungoid growths and fermenting matter, and render the barrel or bottle perfectly sweet and clean.

A pint of the permanganate is a sufficient quantity for a cider or beer barrel. It must be thoroughly rinsed so as to touch all parts of the barrel. Its deodorizing and disinfecting qualities are wonderful, as it contains five equivalents of oxygen, and will even deodorize carbolic acid and remove its pungent smell from the hands immediately.—*Hearth and Home.*

FRENCH ROLLS.—Boil one pint of milk, cut up two ounces of butter into it, add a little salt; when tepid, sift in one pound of flour, one egg beaten, one table-spoonful of yeast; beat these well together; when risen, form into rolls with as little handling as possible. Bake on tins.

PASTE THAT WILL KEEP A YEAR.—Dissolve a teaspoonful of alum in a quart of warm water. When cold, stir in flour to give it the consistency of a thick cream, being particular to beat up all the lumps; stir in as much powdered rosin as will lie on a dime, and throw in a half dozen cloves to give a pleasant odor. Have on the fire a teacup of boiling water; pour the flour mixture into it, stirring well all the time. In a few minutes it will be the consistency of mush. Pour it into an earthen or china vessel; let it cool; lay a cover on, and put into a cool place. When needed for use, take out a portion and soften it with warm water.

Entomology.

Cabbage Butterflies.

Though we recently brought before our readers a short account of many of the insects that are destructive to the cabbage and other allied vegetables, we yet do not hesitate to insert the following interesting article from the pen of Mr. C. S. Minot, of Boston, Mass., which appeared in the last number of our valued contemporary, the *American Entomologist*.

"There is a certain group of butterflies known, scientifically, by the name of *Pieris*, to farmers as 'Garden Whites' or 'Cabbage Butterflies.' They are easily recognized by the following characters: The wings are generally white, with inconspicuous black markings, and occasionally with green or yellow underneath; they are very broad and have no scallops or indentations in the margin; the hindwings in outline resemble an

FIG. 1.

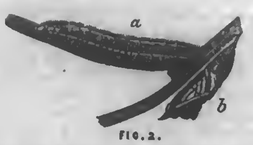


FIG. 2.

egg. The feelers (palpi) are rather slender, but project beyond the head; the antennæ have a short flattened knob. Their flight is lazy and lumbering. The caterpillars are nearly cylindrical, taper a little towards each end, and are sparingly clothed with short down, which requires a microscope to be distinctly seen. They suspend themselves by the tail and a transverse loop, and their chrysalids are angular at the sides and pointed at both ends.' (Harris).

"This genus is interesting, though disagreeably so, to every farmer, for the different species are very destructive to various vegetables: among others, cabbages, nasturtium, mignonette, cauliflowers, turnips, and carrots. We propose now to notice only two of the species, as that number will serve to indicate the habits of the whole genus—which every farmer should be familiar with, so that he may be able to recognize and destroy such dangerous foes.

"The first species we shall mention is the Rape Butterfly (*Pieris rapæ*, Schrank, fig. 1). This insect has been the occasion of some little speculation and great interest to our Canadian and New England entomologists, inasmuch as it has been introduced to this country from England, and is probably one of the most perfect instances on record of any insect being imported from one country to another and becoming completely naturalized in its new quarters. There does not seem to be the slightest doubt that this is the English species. It was probably introduced in 1856 or '57. It was first taken in Quebec in 1859, and in 1863 it was captured in large numbers by Mr. Bowles in the vicinity of that city. As the eggs are laid on the undersides of leaves, it was probably introduced in this form, the refuse leaves being thrown out of some ship; after which the larvæ hatched, and finding themselves in the neighbourhood of their food, ate and flourished. Being, moreover, hardy little fellows, they were perfectly able to endure a change of climate. In 1864 it had spread about forty miles from Quebec as a centre; in 1866 it was taken in the northern parts of New Hampshire and Vermont; in 1868 it had advanced still farther south, and was seen near Lake Winnepesaugee; and finally this last summer it was taken around Boston, Mass., and a few stray specimens in New Jersey. There seems to be no doubt that this destructive insect will, in a few years, spread over the whole of temperate North America; for the other species of the genus have an extensive geographical range, and not being particular as to its food, it will have no difficulty on that score. Indeed, the larva and pupa seem to have an unusual power of accomodating themselves to circumstances,—for instance Mr. Curtis, in his *Farm Insects* of England, states that the caterpillars have been found feeding on willow.

"Now let us look at the larva (Fig. 2, a), and its habits. It is one and a half inches long; pale green, finely dotted with black; a yellow stripe down the back, and a row of yellow spots along each side in a line with the breathing holes. In England and around Quebec it has done immense damage to the cabbages and other Cruciferæ (*Cress* Family) by boring into the very heart of the plant, instead of being content with the less valuable outer portion as some other species are. On this account the French call it the 'Ver du Cœur,' or Heart-worm. When about to transform, it leaves the plants on which it has been living, and fastens itself on the underside of some stone, plank or fence-rail, where it changes into a chrysalis in the middle or latter part of September, and in this stage it hybernates, producing, in New England at least, the perfect insect early in April. The chrysalis, or pupa (Fig. 2, b), is variable in colour, being sometimes yellowish-brown or yellow, and passing thence into green, speckled with minute black dots. The brood of butterflies that emerges from the pupa state in the spring lays eggs shortly afterwards, and these eggs produce caterpillars, which in their turn change to chrysalids in June, and in seven or eight days more the butterfly appears, which again lays its eggs for the second brood, which, as before stated, hybernates in the pupa state.

"In the perfect butterfly the body and head are black, and the wings white, marked with black as follows: In the female (Fig. 1) small space at the tip and three spots on the outer half of the front wings and one spot on the hind wings; beneath, one spot on the front wings, but none on the hind wings, which

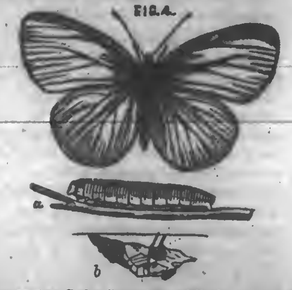
FIG. 3

are commonly yellowish, sometimes passing into green. The male (Fig. 3) has only one spot above and two beneath on the front wings, and a black dash on the anterior edge of the hind wings. There is a variety of the latter sex which has the same markings, but differs from the type in the ground colour being canary yellow. Curiously enough, this variety has been taken both in this country and in England.

"These butterflies occasionally assemble in great numbers. At one time a flight crossed the English Channel from France to England, and such was the density and the extent of the cloud formed by the living mass, that the sun was completely obscured for a distance of many hundred yards, from the people on board a ship that was passing under this strange cloud.

The Potherb Butterfly (*Pieris oleracea*, Boisd., Fig. 4), is the next species to be described. It has a very wide range, reaching rarely as far south as Pennsylvania, extending eastward to Nova Scotia, and at least as

FIG. 4.



far west as Lake Superior, while in the north it is found as high up as the Great Slave Lake in the Hudson's Bay Company's territory. This butterfly has a black body; the front wings are white, marked above with black at the base, along the front edge and at the tip; the hind wings are white above and lemon-yellow beneath, but without markings except a few black scales at the base.

"About the last of May numerous specimens of this species may be seen over cabbage, radish or turnip beds, or patches of mustard, where, on the underside of the leaves, it deposits its eggs These are yellowish, nearly pear-shaped, longitudinally ribbed, and one-fifteenth of an inch in diameter, and are laid seldom more than two or three together. In a week or ten days the young caterpillars are hatched; in three weeks more they have attained their full growth which is an inch and one-half long. Being slender and green (Fig. 4, *a*) they are not readily distinguished from the leaves on which they live. They taper a little towards each end, and are densely covered with hairs. They begin to eat indiscriminately on any part of the leaf. When they have completed the feeding stage they quit the plants and retire beneath palings, etc., where they spin a little tuft of silk, entangle their hindmost feet in it and then proceed to form a loop to sustain the front part of the body in a horizontal or vertical position. Bending its head on one side the caterpillar fastens to the surface, beneath the middle of its body, a silken thread, which it carries across its back and secures on the other side, and repeats this operation until a band, or loop, of sufficient strength is formed. On the next day it casts off the caterpillar skin and becomes a chrysalis (Fig. 4, *b*). This is of a pale green and sometimes of a white colour, regularly and finely dotted with black; the sides of the body are angular, the head is surmounted by a conical tubercle, and over the forepart of the body, corresponding to the thorax of the included butterfly, is a thin projection, having in profile some resemblance to a Roman nose. The insect remains in this stage for ten or twelve days, when the butterfly appears.

"In the last of July and first of August these insects may be seen in large numbers depositing their eggs for a second brood, which wintering in the pupa state, produces the perfect insect the following May.

"This butterfly varies considerably. There are never, we believe, perfectly white specimens, though often nearly so. Again, some specimens have very faint indications of spots arranged as in *P. rapæ;* but on the underside are found the widest limits of variation, for not only do the tips of the front wings become distinctly greenish, or lemon-yellow, and the veins of that portion bordered with grayish scales, but the hind wings may also have the ground colour distinctly greenish, lemon-yellow, or whitish, and the veins display gray scales on each side.

"By taking advantage of the habits of these insects, they might be nearly exterminated. If boards are placed among the infested plants, about two inches above the ground, the caterpillars when about to change will resort to them, and there undergo their metamorphoses. They may then be collected by hand on the underside of the boards and destroyed. As the butterflies are slow fliers, they may be taken in a net and killed. A short handle, perhaps four feet long, with a wire hoop and bag-net of muslin or mosquito netting, are all that are required to make this useful implement, the total cost of which need not be more than fifty or seventy-five cents. The titmouse is said to eat the larvæ, and should therefore be protected and encouraged."

Carrion Beetles.

In a recent article on Water Beetles, we gave an account of two principal families belonging to that group, viz: the Diving Beetles, and the Whirligigs; there is yet another great family of aquatic beetles which we did not then mention, as it belongs to a different sub-tribe of this order of insects; its members are termed "Water Lovers," (*Hydrophilidæ.*) from their habits.

The members of this family live either in the water, or in the damp margins and shores of streams and ponds; they are carnivorous in the larval state, but as beetles they feed upon refuse and decaying vegetable matter, thus uniting the qualities of the two families already noticed, and those of the scavenger beetles, which we now purpose bringing before the reader. A considerable number of these "water-lovers" are found in Canada; some of the species attain a very large size, while others are quite minute, and not to be discerned without close observation. As these creatures are not of any very general interest, we may dismiss them from our notice and pass on to the more conspicuous and note-worthy Carrion Beetles.

These curious and interesting creatures belong to the family *Silphidæ*; they are distinguished by the flattened form of their bodies, their knobbed antennæ, their habits, and the black nauseous fluid they discharge when handled. Their grand duty is to remove from the surface of the earth all dead or putrefying animal matter, which would otherwise become noxious and offensive. They are usually found in or close to carrion of all sorts, though sometimes they devour putrid fungus; occasionally we have taken them on the wing, and have even found them attracted by light into our rooms in summer. The *Silphides* are divided into several genera, the chief of which are *Necrophorus*. including the Sexton or Burying Beetle, and *Silpha*, the Carrion Beetles; both of these genera are well represented in Canada.

The Sexton Beetles (*Necrophorus,*) in spite of their loathsome occupation, are decidedly handsome insects. Their usual colour is deep shining black, variegated with rich orange-red spots; beneath they are frequently ornamented with yellowish silken hair like that of a Humble-bee; their antennæ are very remarkable, consisting of a jointed stem terminated by a rose-coloured or orange knob composed of four little cups or plates piled one above the other. The largest species we have is called the American Sexton (*N. Americanus*, Oliv.); it is nearly an inch and a half long, deep black, ornamented above with large orange-red spots on the head, thorax, and wing-covers, and beneath with light yellow hairs on the breast. It much resembles in shape and general appearance the common species figured in the margin, the

Round-necked Sexton (*N. orbicollis*, Say), but is considerably larger and handsomer. These insects are wonderfully powerful for their size, their flight is vigorous, and they run with rapidity. They are not at all uncommon during the summer months; no sooner, indeed, is any small dead animal or piece of flesh left in a decomposing state on the surface of the ground, than they assemble in troops to bury it. After a careful examination of the object, as if to take its dimensions, and ascertain how many labourers would be required for the job, several of them commence operations by creeping beneath the carcass, and digging away the earth with their fore-legs; they continue their labours till they succeed in sinking it several inches, sometimes nearly a foot, beneath the surface; and at the end of twenty four hours the object is generally out of sight, unless it be particularly large, or the ground difficult to work in. In this labour the males assist, and as soon as it is accomplished, the females deposit their eggs in the carcass. Many curious and interesting accounts have been published respecting the habits and instincts of these creatures,—two interesting naratives of the kind are given in the CANADA FARMER for July 15th, 1868, page 214. A German Entomologist relates that he confined four beetles of this genus in a small space, and supplied them with the following quantity of materials: four frogs, three small birds, two fishes, one mole, two grasshoppers, the entrails of a fish, and two pieces of ox's liver; they succeeded in interring the whole in fifty days. Of course this quantity was much more than sufficient for the nourishment of their future progeny, for whose benefit the burying takes place, and it was probably only because these carcasses were placed within their reach that they continued their burying propensities. (Westwood). As a further instance of their powers, we may mention the following case, related in the *American Entomologist*:—

"On one particular occasion, having deposited a full-grown rat upon newly-moved earth in a particular spot, as a trap for these Burying-Beetles, we found that in twelve hours' time the carcass had been completely buried, all but the tip of the tail, by a single individual of our largest and handsomest species, (*N. Americanus*, Oliv.) a beetle which is only one and a half inch long. It would puzzle an Irish labourer to bury a full-grown whale in the same length of time; yet proportionally this would be a task of precisely the same magnitude."

The Carrion Beetles (*Silpha*, etc .,) differ from the foregoing in their more flattened shape, and dulness of colour, as well as in their habits and minor peculiarities of structure. Our largest and commonest species is the Surinam Silpha (*S. Surinamensis*, Fab.) Its colour is uniformly black, with a transverse irregular, reddish coloured band or series of spots, near the ends of the wing-covers. It is found abundantly in carrion during the summer, and may certainly be considered from its fetid odour and repulsive appearance an exceedingly disgusting, even though highly useful creature. It does not bury its food, like the Sexton Beetle, but may be found swarming in and over exposed carcasses during the summer months, evidently revelling in filth. The handsomest species of this genus is the *Shield-bearing Silpha* (*S. peltata*, Catesby,) which is remarkable for the broad thin expansion of its thorax in the form of an ancient semi-circular shield, of a creamy-white colour, ornamented in the middle with a device somewhat in the form of a cross. We have occasionally taken it in numbers about the body of a dead fish. The larvæ of this genus, unlike those of the preceding one, are obliged to seek their own food, which is of the same character as that of their parents, and consequently have strong legs, and a crustaceous flattened body.

All of these insects, it is hardly necessary to say, in conclusion, are pre-eminently, though indirectly, beneficial to mankind, and therefore should by no means be destroyed.

New Species of Insects.

An esteemed correspondent has written to us as follows respecting a recent article on a new species of insect:—"You speak of this creature as something new under the sun—an insect that had no existence until lately. At least such is the idea I gathered from a hasty reading of your article. While I am not prepared to doubt it, the enquiry arises: Has the Almighty spoken into existence a special creation in this insect, or is it the result of creative laws by which spontaneous creations, so to speak, come forth at proper times? Or has this insect existed during all the past without manifesting its particular propensities until lately?"

We were rather surprised at having such questions put to us by our correspondent, as we thought that everyone knew the meaning of the expression "a new species," when employed by naturalists. It simply means *a species new to science*,—one that has not before been described, or come under the observation of man; not by any means a new work of creation. Since the time when the Almighty Creator "ended His work which He had made," and pronounced it "very good," we do not believe that any new acts of creation have been performed upon our globe, or that any new species of animals have been endowed with life, however much, through His providential care, and through the action of laws which He set in motion, individual species may have been modified in their appearance, ornamentation, habits, food, or mode of life. It has been proved that many species have become *extinct* during recent times, (as, for instance, the Dodo among birds), and undoubtedly this process of extinction has been going on through all time; but it cannot be shown that any species has been *originated* during the observation of the human race. Immense changes are wrought in the appearance and habits of many animals and plants by domestication, breeding, climate, food, etc.; but the species remains the same through all its modifications; and whatever theory we may adopt as to the proximate causes of these variations, whether the fashionable one of "natural selection" or not, we must get back at length to the original fact that "in the beginning God created the heaven and the earth," and that "all things were made by Him, and without Him was not anything made that was made."

Currant-worm Parasite.

We are pleased to find that Mr. J. H. Thomas, of Brooklin, Ont., observed, as much as five years ago, a parasite affecting the larvæ of the Currant-bush Saw-fly; it was probably the same species as that recently noticed in our columns, which we had the gratification of discovering last summer, and which was named by Mr. Walsh *Hemiteles nativorus*. Mr. Thomas writes as follows:—"At the time of which I speak I had a fine yard of red currant bushes, which I found to be literally covered with the larvæ of the Saw-fly. Learning from an old gardener that hellebore would destroy them, I purchased some, and when dusting the bushes spent some time in watching the worms and the effect of the hellebore. While doing so, I several times discovered a small insect resembling a mosquito nearer than anything with which I am acquainted, and yet as unlike that sanguinary animal as any one thing can be unlike another, thrusting its ovipositor into the bodies of the Currant-worms. This they did not appear to relish much, judging from their writhing and twisting during the operation, sometimes letting go their hold upon the leaf and falling to the ground. This ichneumon-fly would thrust its ovipositor into the same worm three times in some cases, in others only once or twice. Seeing the pain, or manifestation of pain, the worms endured, I was half inclined to attack their ichneumon destroyers, which I took these insects to be, and let the worms escape, but concluding that my currant bushes were of more value than the worms, I turned in with my hellebore, and as the boys say 'gave them fits,' for the hellebore made them writhe even more than the ovipositor of the fly. I presume this must be the same as that of which you speak. It was of a dark colour, with long legs; in size between the common mosquito and the ugly beast called by school-boys 'Cock-mosquito,'—a creature not to be confounded with 'Grandfather greybeard,' which in my younger days always told in which direction the cows were by raising one of its long hair-like legs; sure to be correct, point which way it would!"

THE SQUASH BUG.—My last summer's experience in this section with the Squash-bug (*Coreus tristis*, De Geer), showed no difference in favour of any variety of squashes. I raised the "White-bush Scallop" and found them to be as hard on it as on any other kind.

The best means that I hit upon of saving my squashes from the pest, was to remove the earth from the roots of the plants as low as it would bear, and fill up with a mixture of dry ashes and salt. Without this precaution I found them going down into the ground on the under side of the vine, and working where I could not get at them.

In addition to the salt and ashes application, I trimmed off all the leaves that touched the ground as soon as they came down, and spread them out under the plants, and upon examination, mornings and evenings. I generally found about all the old bugs nicely housed away beneath the leaves. I think leaves are far better to trap them under than boards or shingles. A decaying or wilting leaf seems to attract them; you will usually find them on such leaves when looking over your vines.—*J. P. Steele, in the American Entomologist.*

Many plants could not be perpetuated but for the agency of insects, and especially of bees; and it is remarkable that it is chiefly those which acquire the aid of this intervention that have a nectarium and secrete honey.

In some occasional cases, where the nectarium of the flower is not perceptible, if the spur of such a flower, which usually becomes the depository of the nectar that has oozed from the capsules secreting it, be too narrow for the entrance of the bee, and even beyond the reach of its long tongue, it contrives to attain its object by biting a hole on the outside, through which it taps the store.

ATTACKS OF INSECTS AFFECTED BY COLOUR.—Darwin (Animals and Plants, ii. 277) states that "it is certain that insects regulate in many cases the range and even the existence of the higher animals, whilst living under their natural conditions." Under domestication light-coloured animals suffer most; in Thuringia the inhabitants do not like grey, white, or pale cattle, because they are much more troubled by various kinds of flies than the brown, red or black cattle. An Albino negro, it has been remarked, was peculiarly sensitive to the bites of insects. In the West Indies it is said that 'the only horned cattle fit for work are those which have a good deal of black in them. The white are terribly tormented by the insects; and they are weak and sluggish in proportion to the black.'" We should like to learn from our farmer friends whether they have ever observed similar effects of colour upon the attacks of insects in this country. It would be both interesting and useful to know whether such is the case here or not.

Apiary.

Bees—Their Nature and Habits.

As I am daily receiving letters of enquiry about bees, in which many questions are asked concerning their nature and habits, I have thought it best to answer such questions through the journal, for the benefit of all, in a serica of articles under the above heading.

Knowing that many are inclined to doubt a plain statement of facts, because they do not understand how such and such things could possibly have been discovered, or known, I have decided, in stating important facts, to explain how we know them to be facts; which course will perhaps better satisfy all our readers.

I will commence with the queen, or, as called by some, mother bee, from the fact that she is the mother of the whole colony—the only bee in the hive that lays the eggs which produce workers or queens. Though this is a well admitted fact, yet I have met those who doubt it and seem to think that the drones are the bees that lay all the eggs, and that the queen bee should be called a king bee. Others again have told me that they did not believe there was either a king or queen bee for, said they, "we have kept bees for thirty years and have never discovered such a thing;" and they would only be convinced of the fact by our showing them her majesty. That drones do not lay the eggs may be proved by examining a hive any time in the spring before drones appear; as there will be plenty of eggs in the combs, it is certain that some other bee or bees must have laid them. Then to prove that the queen produced them, remove her from the hive, and in four days there will not be an egg in the hive, as all the eggs will in that time hatch and become larvæ. Replace the queen, and in a day or two the combs are again filled with eggs. Hence it is easily proved that the queen is the mother bee of the hive. But there is no real necessity for going to all this trouble, for by killing one each of the different classes of bees, and dissecting them, it is easy to discover even with the naked eye to what sex they belong. A queen bee is produced from the egg in about 16 days, or from the larvæ in about 10 days. To prove this we have only to put a quart of bees in a small box large enough to hold two or three frames six inches square, filled with comb and honey, shut them in, and put them in the cellar, or any dark cool place for 48 hours; take them out at night and open the entrance; the next morning, introduce into this small hive a piece of comb containing eggs but no larvæ and in 16 days they will have produced a queen; or if a piece of comb be introduced containing larvæ not over five or six days old, they will produce a queen in 10 days. By this, it will be seen, that if a queen is removed from a colony the bees will produce themselves another in from ten to sixteen days, and generally in from ten to twelve days, as there are usually both eggs and larvæ in a colony from which a fertile queen has been removed. It will therefore be remembered by those who may desire to remove an Italian queen from a stock, for the purpose of getting queen-cells to put in other stocks, that all such cells must be cut out on the morning of the tenth day after the Italian queen was removed, unless it be early in the spring when the weather is cool. Then it might be safe to leave them until the eleventh day. If left longer than that, some one of the queens will escape from the cell and destroy all the others. Yet it is not well to cut them out before the tenth day, as they are easily injured or chilled, and the operation is not as likely to be successfull, especially in the hands of the inexperienced.

A queen remains in the hive after she has escaped from her cell from five to eight days (if she does not go off with a swarm), and then goes out on her bridal tour to mate with a drone.

IMPREGNATION.

I closed my last by saying that a queen goes out on her bridal tour to mate with a drone from five to eight days after she leaves the cell, provided she did not go off with a swarm. Many are not aware that a queen goes off with a swarm before she has mated with a drone; yet such is the case. As a rule, all swarms that come off after the *first* or *top* swarm, have young queens that are unimpregnated. Hence they must go out to meet the drones after the swarms are hived. I would not be understood to say that these queens will not go out about the usual time, that is, from five to eight days after they escape from the cell; yet going with a swarm may provoke an earlier flight by a day or two, or retard it to the same extent Even when they do not go with a swarm, in some cases, they may go earlier than five days, and in other cases it may be over eight. From five to eight days, however, may be considered the rule, and unless the weather is very fine, and the honey harvest good, it will more likely be nearer the eighth day than the fifth, when the queen goes out. She generally takes wing in the afternoon, when the drones are flying abundantly; and if watch is kept at the entrance of the hive from twelve to two o'clock, the queen may be seen going out or returning. There is generally more or less commotion when the queen leaves, and especially so in small hives made for queen breeding, containing only a few bees. It is necessary to always have brood in the larva state in such hives at the time the queen leaves, otherwise the bees are almost sure to go with her—"swarm out," as it is called, and all be lost. The hives should also contain plenty of honey or feed. As has already been stated, the queen goes out to mate with a drone while on the wing in the air. If she does not meet with one in a short time, she returns to the hive, and remains a while, and then goes out again, and so continues to do until she has become impregnated. This may not take place the first flight or the first day, and she may even require to go the second and third day, if only a few drones are flying; but where there are many on the wing she may meet with one in a short time, and return to the hive. In one instance I saw the queen leave the hive, and in fifteen minutes she returned impregnated. In the act of coition, the organ of the drone is always detached from the body of the drone, and left attached to the body of the queen, and must remain there for a certain time in order that the queen become fertilized; but how long it must remain is not known. It is stated upon very good authority that if this foreign substance is removed shortly after coition, either by the bees or by human aid, the queen will require to mate again. But more of this in our next. By what has already been stated, it will be seen how we know that a queen has mated with a drone. After being fertilized, the queen returns to the hive, not to leave it again, as a general thing, until she goes off with a swarm. The queen does not commence to lay immediately on her return. Generally, forth-eight hours after, or perhaps a little more, eggs may be found in the hive. In some few cases it will be much longer than that. If the colony is strong, and the honey harvest abundant, a young fertile queen will lay from two thousand to three thousand eggs in a day. This is easily determined by putting a swarm containing a young fertile queen into a frame hive filled with empty cards of comb. At the end of four days remove the cards, and find the number of square inches filled with eggs. Multiply by fifty, which is the number of cells to the square inch, and divide by four, and you have the number of eggs laid in a day. The fertility of the queen generally continues for three or four years, when she becomes worthless, laying only drone eggs, and soon dies or is destroyed. It will also be understood that when a queen has become fertilized she never mates with a drone again while she lives; and though it is her nature to mate with the drone on the wing, yet since the introduction of Italian bees it has been the wish of bee-keepers to discover some method by which impregnation could be controlled, and the queen caused to mate with such drones as might be selected. Some time since I stated in this journal that such a discovery had been made by a noted lady apiarian in the United States, and that as soon as I was at liberty to do so, I would publish the secret. I am now at liberty to publish it. In fact, it has already been published in the States. A Mr. Freeman Moore, of Ohio, claims that he made the discovery about the same time. Mrs. Ellen S. Tupper, of Iowa, the lady discoverer, learning that such was the case, requested Mr. Moore to publish his method, which he did in January last. It will appear in my next.

J.H. THOMAS.

Brooklin, Ont

Agricultural Intelligence.

Board of Agriculture.

The Council of the Agricultural and Arts Association met in the Agricultural Hall on Wednesday, Feb. 23, the President, Hon. D. Christie, in the chair.

The following officers were then appointed:—Hon. Jas. Skead, Vice-President; Hugh C. Thomson, Secretary; and Geo. Graham, Treasurer.

The time for the Fall Show was named for the 19th September next.

It was resolved that the Board memorialize the Legislature, asking a remission of duty on animals imported for the purpose of improving the breeds of cattle in this country.

After the reading of a communication from the Secretary of the New York State Agricultural Society on Shade Trees, the consideration of which was postponed, the annual report of the Association was read. This document, which has already appeared in the report of the Commissioner of Agriculture, briefly detailed the Society's proceedings during the past year, all of which are familiar to our readers. The satisfactory progress of the Veterinary College was referred to, and in regard to its present position it was stated that the Council had voted Mr. Smith an annual grant of $150, to assist him in providing Lecture and Dissecting Rooms for the use of the school. In accordance with this arrangement, Mr. Smith has erected a commodious building adjoining his Infirmary, where the lectures are now given, and improved facilities are afforded to young men for acquiring the profession. 28 students are at present attending the lecturer, of whom the greater number design studying the Art as a Profession.

The abstract of the financial report shewed that the total amount received by the Treasurer during the year was $34,527 77, and the total amount disbursed $32,877 80, leaving a balance on hand at the end of the year of $1,649 97.

All the premiums in connection with the Exhibition, and all the admitted liabilities of the Association, had been paid up.

The following gentlemen were appointed to constitute the Executive Committee for the year 1870:—The President, Dr. Beatty, Rev. Mr. Burnett, Messrs. Whyte, Gibbons, Graham and Rykert.

The committee were instructed to make arrangements with the Mayor of Toronto to secure the necessary accommodation for the Provincial Exhibition.

The salary of the Treasurer for the current year was increased to five hundred dollars.

The meeting adjourned till the following day.

SECOND DAY'S PROCEEDINGS.

In the afternoon of the next day the Board again met, and after the transaction of some minor details of business, proceeded to the new building erected for a veterinary college, and listened to an excellent address delivered by the Principal, Professor Smith, in which he reviewed the origin and progress of the school, detailed the course of study pursued, and explained the circumstances which had led to the erection of the present building, in which the students enjoyed the advantage of ample and suitable accommodation for lecture room, museum, and dissecting room, and the structure in its entirety being set apart for the purpose of the Veterinary College would doubtless tend, as it was meant to do, to give greater stability and permanence to the institution, and aid the progress of the Veterinary Science throughout the Province.

At the conclusion of this address, the members of the Board inspected the new building, the stables and outbuildings, and expressed themselves highly pleased with the admirable manner in which all the appointments were arranged.

The members of the Board returned to the Agricultural Hall, and business was resumed.

On motion of Mr. Rykert, seconded by Mr. White, in amendment to the motion made by Mr. Walton on Wednesday, it was decided to hold the Fall Show on the 3rd October next.

The subject of importing seed was then introduced by Mr. Walton, who moved, seconded by Mr. Cowan, "That the Hon. Commissioner of Agriculture at Washington be respectfully requested to place the Council of the Agricultural Association of Ontario on his exchange lists for grain, seeds, &c., with the assurance that the Council of the Agricultural Association will have great pleasure in sending, from time to time, exchanges of all the varieties of grain, seeds, &c., which may come into their possession."

The proposition was favourably received, and the resolution carried. Mr. Farley, however, stated that though he did not object to the proposition, he was convinced from experience that it would never do to import seeds from the South to the North. It would be better to exchange with Scotland or some other northern country. Experience had proved to him that not only seeds, but fruit and other trees from the South never thrived in Canada. The plan, however, was one which involved very little expense.

Mr. Weld said the Genesee and other kinds of wheat, in fact, our best species of grain, were imported from the United States. He also urged his own personal claims in the matter, as one who had for some time devoted particular attention and incurred considerable expense in efforts to import good cereals and other seeds into the country.

The following letter from Hon. Mr. Carling was read:—

"OTTAWA, Feb. 22, 1870.

"SIR,—I beg to submit for your consideration whether a plan might not be adopted which would render the working of the affairs of the Agricultural and Arts Association more economical than at present, without in any degree lessening its efficiency. A valuable library of books relating to Agriculture and Arts is in possession of my department, and the Association also has a very good collection. These might be amalgamated and made more available and of greater use to the public than in the places which they occupy. The working expenses of the Association also seem to be very large; the "miscellaneous" items so much so as to create a general feeling of surprise. The room formerly used for the Legislative library is now unoccupied. It connects with the present Legislative library. The larger portion of it might be fitted up for the united libraries, and the other portion as a meeting room for the Council and Committees of the Association. The joint libraries would be available for use by the members of the Legislative Assembly, during the sittings of the House, and would also be open at all times to the public for reading and reference. The person who would act as Secretary of the Association could also take charge of the library, whilst an officer of my department might act as Treasurer at a small addition to his present salary. This arrangement would be a great convenience, as both officers would then be accessible to the public at all times. The duties of messenger could no doubt be performed by the staff at present employed in the Parliament Buildings without any additional expense, so that the services of the messenger at present employed by the Association could be dispensed with. I have no doubt that, under the proposed arrangement the working expenses would be reduced by at least one half. Besides this, the present Association's building, which I believe is valued at about $20,000, could be either sold or rented, and the annual interest on the proceeds of the sale, or the annual rent, could be appropriated for special prizes in the agricultural or the industrial arts. Will you have the goodness to give to the foregoing your careful consideration, and to bring it before the notice of the Council at its next meeting, which will commence to-morrow—and let me know if any action is taken in regard to it.

"Your obedient servant.

"JOHN CARLING,

"Commissioner.

"To the President of the Council of the Association of Agriculture and Arts for Ontario. Toronto, Ontario."

This communication, which it was stated had only been received that afternoon, elicited a warm discussion, the President contending that the implied charge of extravagance was unmerited; that in the principal item of expenditure that had caused dissatisfaction, namely, Mr. Glackmeyer's claim, Mr. Carling himself, as having introduced that gentleman and recommended him to the Board, was as much responsible as any one, and had shown himself as liable to make mistakes as others. He considered the Commissioner's proposition as the first step towards placing the whole control of the Association in the hands of the Government, and believed that such a result would be disastrous not only to the Association itself, but to the agricultural interests of the country. The Minister of Agriculture, newly

appointed from time to time as the Government changed, would scarcely ever be practically acquainted with the interests and requirements of the farmer, and it would be far better that the Association should be altogether independent of Government aid, than that it should be thus merged into the Bureau of Agriculture.

Professor Buckland explained that Mr. Carling deplored and condemned Mr. Glackmeyer's exorbitant charge as much as any one, and could assure the Board that the Commissioner had no intention whatever of interfering with the independence of the Association. He entirely agreed in the principle enunciated by the President that the Board should have no connection with parties, and nothing to do with politics.

After much animated discussion, it was resolved to postpone the further consideration of the subject till the next meeting.

A communication from the Ontario Poultry Association, asking for a grant of one hundred dollars per annum from the Agricultural Association was, at the suggestion of Mr. Rykert, allowed to stand over for consideration at the next meeting.

IMPORTATION OF CATTLE.

The SECRETARY submitted the following memorial to the Senate for the approval of the Board:—

To the Honourable the Senate of the Dominion of Canada, in Parliament Assembled:

The Petition of the Council of the Agricultural and Arts Association of the Province of Ontario,

HUMBLY SHEWETH:

That great benefit has heretofore resulted to the Agricultural interests of Canada from the importation from Great Britain and foreign countries, of animals of superior breeds for the purpose of improving the existing breeds of the country, and that the general prosperity of the country has been thereby promoted.

That there is much risk and expense involved in the importing of such superior animals, and that therefore it is highly desirable that such importation should not be burdened with any additional cost which can be avoided; but that on the contrary, it should be encouraged by a liberal policy on the part of the Government.

That the existing Customs duty of $15 per head on horses, and $10 per head on horned cattle, $1 per head on sheep, and $2 per head on swine, tends to discourage the importation of superior animals for breeding purposes, and thereby retards the progress of one of the most important interests of Agriculture, without being of any corresponding advantage to the public revenue.

Your petitioners therefore pray that such duties may be remitted in so far as they relate to animals of superior breeds imported for breeding purposes.

And your petitioners, &c. &c.

The memorial was adopted without discussion.

Some farther business of an unimportant nature was then disposed of, and the meeting adjourned till the 1st of June next.

Mark Lane Harvest Reports.

The *Mark Lane Express* has a lengthened article on the harvest returns of the past year, embracing in the estimates the crops of the European and American continents, and concludes that the present low prices for grain cannot be maintained during another season. It does not anticipate any immediate or sudden rise.

"But during the summer and early part of autumn," it observes, "we most assuredly (even under the most favourable prospects for the crops) expect a smartish rise, which will increase in intensity should anything occur to endanger the growing crops. Prices being low, cannot well go much, if anything, lower, but owing to their low standard, there is plenty of scope for a smart reaction upwards."

In a rather long review of the season in England, it is said that of fall wheat a somewhat larger breadth than usual was sown, but less (in fact for a series of years there has not been so little) spring wheat sown. As to the yield, it is said that "On the whole the wheat crop is considered 10 to 15 per cent. below an average, or twenty-five to thirty per cent. under that of 1868. In Wales, crops satisfactory in quantity and quality." In Scotland "what may be called nearly an average, though about 20 per cent. below that of last year; but quality and condition various." In Ireland there was about 4,033 acres less land sown to wheat; and "on the whole, the yield is about 15 or 20 per cent. below an average." In summing up it is said: "Taking everything into consideration, it is thought the yield of wheat in Great Britain and Ireland is one-eighth below an average, and that owing to diversity in quality more fine wheat will be wanted, and that an importation equal (in round numbers) to eleven million quarters of wheat and flour will be required."

There are detailed reports from other countries, but we only have room to state that in France the crop of wheat is called ten per cent. under an average in quantity, quality fine, but with the old stocks is supposed to have enough. Holland will have to import more or less, as usual; it is thought she will require even more foreign aid than last year. Belgium will require fully as much, if not more, than last year. Switzerland will require her customary assistance. Germany is said to be able to spare one and a quarter millions of quarters, against one and a half last year. Russia is considered as able to spare the same as last year, which was one and a half million quarters, although, if prices do not improve, the exports may fall short of this amount. In Austria and her provinces the crop is not so good, or two-thirds to three-quarters of an average. In Hungary, thirty to fifty per cent. under an average. Last year the exports were put at one and a half millions, this year at three-quarters of a million wheat and flour. Reports from other countries are also given, but perhaps the above, condensed in the columns of the *Country Gentleman*, is enough to show the present supply of, and demand for, wheat in Europe, while it will give a much better understanding of the facts than the usual accounts and reports in the newspapers.

Testimonial

At the last annual meeting of the West Northumberland Agricultural Society it was resolved to present their Secretary, Charles Bourn, Esq., with some suitable testimonial, in token of the appreciation by the members of his long and faithful services to the Society. The testimonial consisted of a handsome mother-of-pearl inkstand, holding two beautiful cut-glass ink bottles, and a splendid gold pen and ebony holder. The presentation was made by G. Bennett, Esq., (late President of the Society), and the Treasurer, W. Riddel, in the name of the Society. Mr. Bennett paid a warm compliment to Mr. Bourn for the very efficient, zealous, and punctual manner in which he had discharged the duties of Secretary for the last twenty-one years. In all that time nothing could exceed the very satisfactory manner in which the business of the Society had been conducted, and this testimonial was presented to him, not so much on account of its intrinsic value, but as the most suitable means of giving expression to the regard and esteem in which he was held by the members of the Society. The speaker hoped he would long be able to use the pen in their service, and concluded with best wishes for the welfare of Mr. Bourn and family. Mr. Bourn in reply feelingly acknowledged this mark of approbation from the Society of which he had been elected Secretary for the twenty-second time, and said that while discharging the duties of his office, though his labours had been sometimes arduous, he had felt them less from the deep interest he always took in all agricultural matters; that during his long connection with the Society, he was happy to say he had formed many pleasant acquaintances, and made many sincere and warm friends; but that he had also been called upon to mourn the loss, by death, and removal to other parts of the country, of many active and useful members of the Society; that it would always give him pleasure while he lived to look upon this testimonial just presented to him, and that he trusted it would descend as an heirloom to his family, who, along with himself, would look upon it with feelings of gratification and pride. He concluded with heart-felt thanks for this token of esteem and approval from the Society.

The presentation took place at the North American Hotel, Cobourg, a number of the leading members of the Society being present, also several members of the County Council, which was in session at the time.

Agricultural Meetings—Fall Shows.

In accordance with invitations issued by the Directors of the Darlington Agricultural Society, a meeting of representatives from the various County and Township Societies was held in the Council Chamber, Bowmanville, on Tuesday, 25th January, for the purpose of arranging for the holding of Fall Exhibitions in connection with each of the Societies, in such a manner that the fairs may not clash with one another, as heretofore.

The following Societies were represented: East Durham; Hope; West Durham; South Ontario; Clarke; Darlington; Cartwright; Whitby; Pickering.

The meeting was organized by appointing Mr. N. Choate, chairman, and Mr. R. Windatt, secretary.

The Secretary of the Bowmanville Horticultural Society, W. R. Climie, was requested to take part in the proceedings.

The holding of County Fairs was first considered, and the following days selected:

South Ontario—First Tuesday and Wednesday of week following the Provincial Exhibition week.

West Durham—Thursday and Friday of same week as Ontario show.

East Durham—Tuesday and Wednesday of second week following Provincial Exhibition week.

The days for Township Fairs were fixed on as follows:—Pickering and Clarke on the Thursday and Friday of second week following Provincial Exhibition; and Cartwright on Thursday of same week.

Whitby and Hope on the Tuesday and Wednesday of third week as above; and Darlington on Thursday and Friday of same week.

The Secretary was instructed to communicate to the Markham and North Ontario Agricultural Societies the above arrangement, and request them to fix the days for their shows so as not to interfere with the decision arrived at by delegates.

The question of the appointment of Judges for the several fairs was next considered; and after some little discussion, the following resolution, moved by Mr. Foote, seconded by Mr. Bickell, was unanimously adopted:—

That, in the opinion of this meeting, the best mode of securing judges will be, for each of the Boards of Directors to apply to their neighbouring society to send as many judges as they may require at their respective exhibitions—the travelling expenses to be paid by the societies receiving the said judges.

COUNCIL OF THE AGRICULTURAL ASSOCIATION.—The four members of the Council who retired in rotation have all been re-elected with the exception of the late President, in whose place Mr. James E. Farley, of Thurlow, has been chosen by the Agricultural Societies of the division formerly represented by Mr. Mallory. The contest, we understand, was very close, and the majority in favour of the successful candidate a very small one.

TO THE FARMERS OF CANADA.

WILSON, BOWMAN & CO.,
Hamilton, Ont.,
MANUFACTURERS OF THE CELEBRATED

LOCKMAN SEWING MACHINE

TAKE pleasure in announcing that the popularity of the Sewing Machine manufactured by them is still on the increase. They are now turning them out at the rate of 600 per month, and yet have been compelled within the last two weeks to increase their facilities to a capacity of one thousand per month.

The Lockman Machine, from its capacity to sew the heaviest fabrics with linen thread, as well as the finest cambrics with No. 150 cotton, is pre-eminently the FARMER'S FAVORITE FAMILY FRIEND. It is so exceedingly simple in its parts, and so strongly and durably made, that it does not require a mechanical genius for its management.

The manufacturers challenge the world to produce its equal, and yet its price is from FORTY TO FIFTY PER CENT LOWER than that of any other First Class Lock Stitch Sewing Machine.

Every Machine is warranted by the manufacturers, who are determined that no inferior machine shall leave their premises. Parties purchasing to sell again, can obtain liberal terms by addressing the manufacturers.

MILLER'S TICK DESTROYER.

MILLER'S TICK DESTROYER.

MILLER'S TICK DESTROYER.

FARMERS are recommended to give this valuable preparation a fair trial, as in eradicating all affections of the skin to which Sheep are subject. It operates promptly and effectually in destroying Ticks and other vermin pests, as no Sheep-owner should be without it. As a certain cure it has hitherto proved infallible.

Other Dips may kill all vermin seemingly alive, but on examination after a short time, will be found to be as full of Vermin as ever. The Tick Destroyer penetrates to the Vermin in all grades of development, extinguishing both hatched and unhatched life.

Delivered to Great Western Railway, at Hamilton, and warranted pure and true to name. Orders accompanied with the cash booked in rotation, and filled in the spring as soon as the weather will permit. Address, LEWIS BRIGDEN, Hamilton, Ont. 2-3t

BEE-KEEPERS in Canada may rest assured that J. H. Thomas' Prize Bee Hives are the best made in America, they are cheap, durable, and perfect. Last [illegible] from Nova Scotia, and from [illegible] the demand is increasing yearly. Since they were brought before the public a number of other hives have been brought forward, many of which are entirely worthless; some are good; but not one possesses as many advantages as the Thomas Hive, nor is any so simple in construction. In a word, as a Bee-hive, it is unsurpassed. Send in your orders, always accompanied with the money, and they will receive prompt attention.

Single Rights [illegible] following prices Single and Double Rights to make and use both Double and Single Boarded Hives, with a full printed description thereof:—

Single-Boarded Hive	$5
Double-Boarded Hive	6
Single-Boarded Observing Hive, Glass in 1 side	6
" " " 2 sides	7
Double-Boarded Observing Hive, Glass in 1 side	7
" " " 2 sides	8

All persons purchasing a Hive at above rates, which always includes the right to make, and preferring to order Hives from [illegible] rather than make, will be supplied at the following rates:—Double-Boarded, $3 50; Single-Boarded, $2 50; or, if ordered in lots of three, to one address, Double-Boarded, $3 25; Single-Boarded, $2 25; in lots of six, Double-Boarded, $3; Single-Boarded, $2. Individual rights, without the Hive, $2. Hives sent safely, as freight, by rail to any part of Canada. Three Hives sent to one address for the same freight as one Hive. Bee-keepers would do well to form clubs, and order three or more Hives sent to one address, and thereby save freight.

Hives at the above rates are made with one honey-box. Persons ordering Hives made with two honey-boxes, must send 25c. more for each Hive; with three honey-boxes, 50c. more for each Hive.

"THE CANADIAN BEE-KEEPER'S GUIDE" always on hand. No Bee-keeper should be without it. Price, post-paid, 25c. To parties wishing to purchase territory, I make this offer—Any person sending me ten orders for the Single-Boarded Hive, at $5 each, from any one Township, will receive in return the ten Hives to fill his orders, and the right of the Township for himself. Now is your chance.

H. THOMAS,
v2-14t Brooklin, Ont.

GREAT REVOLUTION IN BARN BUILDING. Cheap and Handing of all kinds of Grain, accomplished by John Dennis' Patent Invention of 1869, by which the following advantages are obtained. Firstly—Barns can be built on this system for less than half the cost on the old plan. Secondly—One man and a horse, with the patent Lobo Annihilator, can unload more hay or grain in five minutes than five men can in half an hour. Thirdly—These barns are [illegible] for a number to build in, by hand, hay-forks, or Lobo Annihilator. Amount of timber and lumber reduced to board measure to build barns of the following capacity:—For a barn, 32x50, 11,000 feet; 3 barns, 30x50, 47,000 feet; for 1 barn, 50x50 feet, and two sheds, 20x50 feet each, with side walls 24 feet high, and roof half-pitch, 20,000 feet for the three buildings; time to frame first barn, 3 men, 11 days; second, 3½ do., and for the large barn and two sheds, less than 5 days. Let no man in the Dominion get out timber for a barn without first coming to Newmarket, County of York, (which will not cost much) and see one of these barns with the two sheds attached, and with the unloading machinery in full operation; he can judge for himself, and after seeing it, if he does not say that it is the best and cheapest barn he has ever seen, I will pay his fare home. Carpenters who are now building barns should secure rights at once, as after these barns are seen no other kind of barns will be put up, for two reasons—they are cheaper and better.

Address JOHN DENNIS, Patentee,
v2-1-4t Newmarket, Ont.

TO STOCK BREEDERS AND AGRICULTURAL SOCIETIES.

I INTEND to keep a Register Book in which to enter all Thoroughbred Stock for sale, and to purchase or sell on commission, and as my personal attention will be given to selection, I trust to be favored with orders from those wishing Pure Stock. Address

DOMINION OF CANADA

V. R.

EMIGRATION
TO THE
PROVINCE OF ONTARIO.

To Capitalists,
Tenant Farmers,
Agricultural Labourers,
Mechanics,
DAY LABOURERS,

And all Parties desirous of Improving their Circumstances by Emigrating to a New Country.

THE attention of intending Emigrants is invited to the great advantages presented by the Province of Ontario. Persons living on the interest of their money can easily get eight per cent. on first-class security.

Tenant Farmers with Limited Capital

Can buy and Stock a Freehold Estate with the money needed to carry on a small farm in Britain. Good cleared land, with a dwelling and good barn and outhouses upon it, can be purchased in desirable localities at from £4 to £10 Stg. per acre. Farm hands can readily obtain work at good wages. Among the inducements offered to intending Emigrants, by the Government, is

A FREE GRANT OF LAND
(WITHOUT ANY CHARGE WHATEVER.)

Every Head of a family can obtain, on condition of settlement, a FREE GRANT of two hundred acres of land for himself, and one hundred acres additional for each member of his family, male or female, over eighteen years of age.

All Persons over 18 years of age can obtain a FREE GRANT OF 100 ACRES.

The Free Grants are protected by a Homestead Exemption Act, and are not liable to seizure for any debt incurred before the issue of the patent, or for twenty years after its issue. They are within easy access of the front settlements, and are supplied with regular postal communication.

Registers of the Labour Market

And of Improved Farms for sale, are kept at the Immigration Agencies in the Province, and arrangements are made for directing emigrants to those points where employment can be most readily obtained. Several new lines of railway and other public works are in course of construction, or about being commenced, which will afford employment to an almost unlimited number of labourers.

Persons desiring fuller information concerning the Province of Ontario, are invited to apply personally, or by letter, to the Canadian Government Emigration Agents in Europe, viz.: Wm. Dixon, 11 Adam Street, Adelphi, London, W. C.; J. G. Moylan, Dublin; Charles Foy, Belfast; David Shaw, Glasgow; and E. Simays, Continental Agent at Antwerp.

Also to the Emigration Agents in Canada, viz:

John A. Donaldson, Toronto; R. H. Rae, Hamilton; Wm. J. Wills, Ottawa; Jas. Macpherson, Kingston; L. Stafford, Quebec; J. J. Daley, Montreal; E. Clay, Halifax, Nova Scotia; Robert Shives, St. John, and J. G. G. Layton, Miramichi, New Brunswick, from whom pamphlets issued under the authority of the Government of Ontario, containing full particulars in relation to the character and resources of, and the cost of living, wages, &c., in the Province, can be obtained.

JOHN CARLING,
Commissioner of Agriculture and Public Works for the Province of Ontario.

Department of Immigration,
Toronto, October, 1869. 2-12t.

Markets.

Toronto Markets.

"CANADA FARMER" OFFICE, March 14, 1870.

Sheepskins—75c. to $1.40.
Wool—23c. to 25c.

New York.—*Flour*—Steady; receipts 6,000 bbls.; sales 7,000 bbls at $4 75 to $4 90 for Superfine State and Western; $5 05 to $5 85 for common to choice Extra State; $5 to $6 for common to choice Extra Western. *Rye Flour*, Firmer at $4.40 to $5.50. *Wheat*, without decided change in price; receipts 12,000 bush.; sale 16,000 bush. at $1.60 to $1.70 for choice white State. *Corn*, firm; receipts 4,000 bush.; sales 10,000 bush. at 92c. to 95c. for new mixed Western. *Barley*, Dull; sales 2,000 bush Canada West at $1.12. *Oats*, quiet; receipts 10,000 bush.; sales 16,000 bush. at 55c. to 56½c. for Western. *Pork*, firmer at $26 to $26.25 for new mess. *Lard*, Heavy at 14¾c. for steam, and 15¾c. for kettle rendered. *Butter* steady at 14c. to 26c. for Ohio; 26c. to 46c. for State. *Cheese*, Dull at 10c. to 13c. for common to prime.

PROVINCIAL MARKETS.

Montreal.—*Flour*—Extra, $4.40 to $4.45; Fancy $4.20 to $4.25; Bag flour, 100 lbs., $1.80. *Wheat*, Canada fall, 90c. to 96c.; Spring, 90c. to 92½c. *Oats*, per 32 lbs., 25c. to 27c. *Barley*, per 48 lbs., 40c. to 45c. *Butter*, dairy, 17c. to 18c. *Pork*, Mess, $23 75 to $24; *Dressed Hogs*, $6 50 to $6 75. *Peas*, per 66 lbs. 70c.

Collingwood.—There is very little alteration in our market prices this week. Spring wheat 68c. to 72c.; fall wheat 70c. to 74c.; *Barley* 35c. to 38c.; *Oats*, 25c.; *Peas*, 40c. to 42c.; *Pork*, $5 to $7.50; *Butter*, 16c.; *Eggs*, 13c. to 14c.; *Potatoes*, 25c. to 28c.

THE CANADA FARMER is printed and published on the 15th of every month, by the GLOBE PRINTING COMPANY, at their Printing House, 26 and 28 King Street East, Toronto, Ontario, where all communications for the paper must be addressed.

Subscription Price, $1 per annum (POSTAGE FREE) payable in advance.

THE CANADA FARMER presents a first-class medium for agricultural advertisements. Terms of advertising, 20 cents per line space. Twelve lines' space equals one inch. No advertisements taken for less than ten lines' space.

Communications on Agricultural subjects are to be addressed to "*The Editor of the Canada Farmer*," and all orders for the paper are to be sent to

GEORGE BROWN,
Managing Director.

THE CANADA FARMER.

VOL. II. No. 4. TORONTO, CANADA, APRIL 15, 1870. NEW SERIES.

The Field.

Early Spring Work.

Although March but lately held stormy sway, the busy time of the tiller of the soil is already upon him, and as work well begun is easiest finished, it will be well for him to make his preparations as early as possible. While the weather is still unsuitable for out of door operations, and the Frost King holds fast his grip, much can be done in the barn.

SELECTING AND CLEANING SEED should now be attended to. We have before spoken of the importance of having only the best seed to sow. Let everything intended to be used for this purpose be selected and cleaned with scrupulous care, every light seed and foul weed being driven out. The fanning mill is not used half as much as it should be, and too often the work is delayed so long that when the time comes it is but half done. Let a calculation be made of the exact quantity of grain or grass seed required for every field to be sown, and the quantity made up only of what has been carefully run through the fanning mill, and if necessary hand sifted, and put up in bags and labelled to show what field it is to go to. Then when the time comes for seeding, there will be no confusion and loss of time about the matter. This done, attention must next be given to the

IMPLEMENTS.—The ploughs, harrows, cultivators, &c., should get a good overhauling to see that they are all in proper order, and if necessary any repairs made. Brighten up the mould-boards of the ploughs with sand and water, and give a coat of crude petroleum to the woodwork, to prevent the rain from soaking in. See that all the clevises, whiffletrees, trace-chains, and other small things so often needed when work commences, are in good order, and put together in a place where they can be easily found when wanted. Have the harnesses all made sound and tight, and let them be well oiled.

MANURE.—Anything intended to be used as a portable manure, such as land plaster, bone dust, salt, etc., should be stowed away in the barn, or some outbuilding proof against wet, to be ready on hand when the time comes for its use.

As soon as the spring thaw sets in, and while the land is yet too wet to be worked, is the time to get the barn-yard in order. Have all the manure made during the winter forked over, and thrown or drawn into a covered shed, or if that is not to be had, into large heaps round the sides of the yard, so as to leave a clear space in the centre, and the stables, byres, etc., free from foul obstructions. The heaps should be so made as to be high, and with perpendicular sides, to prevent the stock getting on them. As they are made, it will be well to throw six inch layers of muck, or even loam earth, about each two feet thickness of the manure heap. The whole can then be covered with the scrapings of the bottom of the yard. When that is done, cover the whole centre of the yard with a fresh layer of muck or earth, to absorb urine and the washings from the manure heaps, and that again with clean straw, so that the stock can enjoy cleanliness and comfort out of doors when the mild days come, and confinement gets irksome, just before grass is ready. This last layer will help to make manure for the fall, or the late sown turnips.

PEAS are usually the first crop sown. See that your seed is free from bugs. If not, it is much reduced in value, though many of the germs may still remain, but they will produce little, weak, spindling plants. Get the best and most productive kinds, such as the "Crown" or "Daniel O'Rourke." Even if it should cost more for seed, an extra fifteen or twenty bushels per acre will much more than pay for an increase of double in the price of the seed. This crop is always a paying one.

SPRING WHEAT comes next in order. A good deal will be grown, notwithstanding the low price at which it sells. Indications point to a serious loss from winter-killing in the autumn sown wheat this year, and it would not be well to leave the country with a short supply of the "staff of life." Be sure to brine or lime the seed to prevent smut. Let the land be made deep and mellow.

BARLEY.—The failure to realize good prices on last year's crop, resulting from lack of quality, will, no doubt, discourage many, and those who do grow the crop this year will reap the benefit of higher prices next Fall. This crop requires a rich warm soil rather than a deep one, and the more its roots can spread near the surface, and yet find plenty of food, the better will it succeed. Still, barn-yard manure is seldom good for it, unless old and very finely composted. It is better applied to the soil through the previous crop, in roots, potatoes, or corn, or, as is done by some first class growers, thoroughly incorporated into the soil early in the autumn. Barley should not be sown too early, in fact, not till the weather has become settled and warm, and the soil acquired a temperature sufficient to ensure rapid germination of the seed, and a quick, steady growth of the plant after germination takes place. The shorter the time it occupies the ground the better will the crop be likely to prove. Superphosphate or very fine bone dust is a most excellent and profitable manure to apply to barley, say at the rate of 100 lbs. per acre if drilled in with the seed, or 200 lbs. per acre if sown broadcast.

Oats.—There is much to be made on this crop, especially by the class of farmers who sell by measure, have their lands overrun with thistles, and wish to propagate them by growing a late ripening crop. Of late much interest is being taken in the matter of introducing new varieties of this grain, supposed to be of more productive quality than the old sorts, but notwithstanding the stories told by interested parties of the large yields given by some of the new kinds, as the Surprise, Norway, Excelsior, and others, we have doubts if any of them are better even in this respect than some of the old sorts, while some of them, at best, are of very light weight in proportion to their bulk. Oats are a crop always sure to give large returns on good soils with proper culture—things seldom accorded them.

Potatoes will probably not be grown to such an excess as they were last year, resulting in such very low prices. The very early sorts, if grown near the cities and towns, and planted sufficiently early to mature by the end of June or first of July, are most profitable, though rather too troublesome a crop for the better class of large farmers, who will naturally value their time higher than to be peddling out early potatoes in the market. Arrangements might, however, be made to sell the crop in bulk to some enterprising dealer, who will take the trouble of doing the marketing.

Corn.—Those who can grow corn to advantage should not neglect to get their land for it into good condition and fine tilth as early as possible. Good crops, if not the very best, are most certain on a strong stiff sod or clover ley, first heavily spread with barn-yard manure, and then ploughed under somewhat shallowly, say 4 to 6 inches, and planted to corn not later than the 24th of May. Corn requires at least 100 days from the time of planting to fully ripen, under favourable circumstances, and it is most desirable to select varieties that will ripen in that time if possible. By care in selecting the earliest ripening ears each season, and planting only the seed from them, there is no doubt something might be done towards obtaining earlier maturity in this crop.

Clover and Grasses.—Clover seed is scarce and expensive, yet it will be poor policy to neglect sowing, or to give but a thin seeding, on that account. The most of failures to get a stand we think due partly to want of using enough good sound seed, but also greatly to the want of having the land in good tilth, and neglect to cover the seed when sown. Barley is undoubtedly the best crop on which to sow clover, as the land given to this crop is usually the cleanest, richest, and best prepared of any. Sow the seed immediately after the last harrowing in of the barley, and cover by dragging once over the surface, crosswise of the last harrowing, a bush harrow made of the tops of some trees, bound together at one end, and spreading out at the other; a slight chain and whiffletree is attached, and one horse does the work. This plan will cover the seed lightly, which is all that is needed. A smart rain coming on immediately after the clover seed is sown will often cover it enough, if the soil is friable and in good tilth. If it is desired to make a strong wheat soil into meadow land, timothy alone, or with very little clover, is best, and it can then be sown either on winter wheat immediately after, or just when the snow melts, or on a spring crop of grain directly after seeding. No artificial covering is needed for timothy. For permanent pasturage to be used for stock, we would much prefer leaving out both timothy and red clover, and sowing a mixture of several kinds of grass seeds, with the addition of some five or six pounds per acre of the *small* Alsike clover. In this case the grass seed must either be sown on a barley crop, or on land specially prepared exclusively for the purpose, and be covered in with the harrow.

Stock must now be well looked after, and have some roots, in order to prepare them for turning to grass when it is ready, and so prevent scouring. The horses must be kept on dry provender, and in solid condition, to enable them to stand the hard spring work. Cows should not be allowed to roam about the yards, except for two or three hours a day when dry, nor sheep to get drenched in rain storms. Sheep generally get the first to grass, cattle after, and horses not till their work-days are over. Do not be in too much of a hurry to get the spring ploughing done, and so keep men and horses at work in the rain; and especially avoid turning over the soil when it is so wet as to pack as it leaves the mould-board.

Science and Farming.

In a late article under the head of "What has science done for the farm?" a short history, or rather a very brief sketch, was given of the way in which phosphatic manures came to be introduced into England. Things are not yet arrived at that state in Canadian farming when more than a slight sketch is admissable on these subjects. Matters are progressing, however; crops are failing, assistance to the farmer is demanded, and assistance can only be had through the aid of science.

While the search after phosphates was progressing, until not only the shingles, and ancient deposits of bones, but even the old battle fields, were diligently searched and rifled of their contents, and all ground up and converted into superphosphate, or simple bone dust, science had shown that there were other sources of ammonia to be found than the guano islands. The liquids resulting from the distillations of gas works were found to be specially rich in this substance, and the conversion of these liquids into ammonia, in one shape or another, now forms an immense business throughout the civilized world, wherever gas is used as a means of light.

The immense plains in different parts of the world which yield nitrate of soda, and also the various sources of nitrate of potash, were most industriously laid under contribution. The waste of every animal production was equally searched for and husbanded; old cloth and woollen goods gone too far for the shoddy mill; the refuse of the shoddy mill itself; the remains and refuse of slaughter houses; enormous quantities of the refuse of fish after the extraction of the oil; every animal substance which by the aid of chemicals could be put into such a state as to be concentrated and conveyed, as an article of merchandise, from one point to another; all are now utilized, and by scientific aid are converted to the use of the British and European farmer. But the mainstay and aid to the manufacturer of chemical manures has been sulphuric acid; this, from its solvent action and powerful affinities, and from its cheapness, is employed on every occasion, and the sulphur which was formerly used chiefly for the manufacture of gunpowder, and the destruction of human life in war, is now the beneficent agent from which the present fertility of England is obtained.

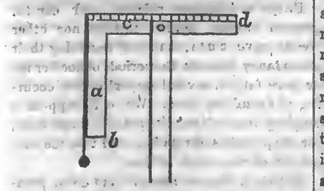
Fifty years ago, sulphuric acid was an expensive chemical agent, useable only for special chemical purposes, and considered cheap at ten times its present price. Now, it is an object of every-day use, not only in the chemical laboratory, but in all manufactories, and on many farms, and the home manufacture of superphosphates is now very common in Britain. Indeed, no modern farm of any pretension is to be found where its use is unknown. It was at one time manipulated by chemists only, and even by them with dread. Now it is used on a large scale by men only one degree above common labourers, and by its potent aid matters are unlocked from stony substances totally inert in their natural state, but which afford the highest possible assistance to the farm when separated and rendered soluble. Formerly the only source of potash was the ashes of burnt wood; now the feldspar which is so plenty in some forms, and indeed in most forms of granite rock, is profitably used to obtain potash manures. Almost all the soda of commerce is obtained by the action of sulphuric acid on common salt, and the latter in its various modifications now enters largely into the formation of chemical manures. Salt and lime mixed together and turned over for three months form the most active substance known for reducing vegetable matters and farm-yard manures into the substance usually known as "rotten dung." These matters, when mixed with lime and salt so prepared, decay in one-fourth of the time they would otherwise take to fall into the most profitable shape as manure; and the action of these chemicals does not cause a loss of ammonia, or other fertilizing salts, to any serious extent.

Science has also pointed out to the farmer the benefits of liquid over solid manure; the necessity of keeping our heaps and reservoirs of manure from the leaching action of the rains; the reasons for the necessity of rotation of crops; and, indeed, it may be fairly claimed for science, that, through its aid, the average production of grain per acre throughout Great Britain has doubled itself within the last twenty years. VECTIS.

Practical Drainage

BY ALAN MACDOUGALL, C.E.

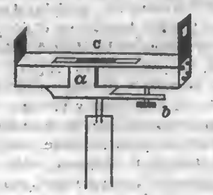
The next step towards a scientific instrument for obtaining levels is somewhat similar to the one mentioned before. Instead of having the head fastened on like a T, it has a square fastened on, with a plumb-bob attached to the perpendicular



arm. The square may either be fastened on firmly, or have a thumb-screw to allow of its being loosened or tightened, as may be required. The plumb-bob is made to hang down the side of the arm *a* in the same way as it hangs on the centre line of the T, and when it just touches the arm *a*, the other arm c is level. Some persons use this square with the arm graduated to inches, then by throwing it slightly off the level, a grade is obtained. For example, if the arm c were thrown a quarter of an inch off the level, and its length were 24 inches, then a quarter of an inch on 24 gives one inch in 96, or a grade of 1 in 96. This needs very careful handling and calculation, and for this purpose the arms must be of the same length, so that whatever distance is required to be laid off can be accurately measured. If not, and the arm *a* were 12 inches long, while the arm c were 24, let the point *b* be shifted a quarter of an inch, the point *d* will move through *twice* that distance, so that instead of obtaining a grade of 1 in 96, the grade obtained will be 1 in 48.

If it be desired to use this square and bob for laying out grades, the upright must be firmly set in the ground, and after the grade has been laid out, the arms must not be touched, in case any derangement to the grade takes place. It will answer pretty well on a perfectly calm day, but if there be any wind to sway the plummet about, then this method of laying out a grade is not very practicable.

Considerable accuracy in levelling can be obtained in the use of the undermentioned instrument. It is often used in levelling long distances for drains. It works with sufficient accuracy to be recommended as the nearest approach to an engineer's level that it is necessary for



a drainer to have. It consists of an ordinary spirit level, having an eye-sight raised above each end. At one end the sight is higher than the other, and is furnished with a piece of stained glass, or some other material of the same height as the other sight. The level is made to fit into a brass frame *a*, which acts as a spring to adjust it to the level position *c*, by means of a large-headed screw *b*. A stud, projecting from this frame, is to be firmly pushed into a gimlet hole on the top of a short staff, which is firmly driven into the ground. When not in use, the level can be carried in the pocket, as it is of no weight, and the staff used as a walking stick. It is preferable to have the frame with the spring attached to the level, for the convenience of carrying it. Even a better method than having the spring *a* and adjusting screw *b* is to have the stud fastened on the bottom of the level and made to fit on a core working on a ball and socket joint, like the working of a surveyor's compass on the "Jacob staff." It is rather more costly perhaps, but makes a more permanent level, and it can be very accurately levelled by the hand.

In every case, the sighting is to be done in the same way, which is similar to that formerly explained in the use of borning rods, the target on the graduated rod is to be moved up or down until it cuts the line of vision, and the difference in heights of the readings on the staff and the height of the level above the ground to be taken, which difference will be the difference of level between any two points.

Tile Drainage.

To the Editor.

Sir,—A circumstance has come under my notice respecting a tile drain, to which I should like to draw your attention, and that of your numerous readers.

The drain leading from the cellar of Mr. F. Coleman, in this neighbourhood, became completely blocked up. On examination, it was found that the fibrous roots of an apple tree, growing some thirty feet from the drain, had entered the crack between the tiles, and had become a mass so solid that the water could not pass. I enclose a portion for your inspection.

The drain was laid three years ago, by a professional hand from England. The tiles were two inch bore, laid four feet deep.

There is an orchard of ten acres in this vicinity, with tile underdrains. It has two main outlets, and in the spring does not run two barrels a day from either outlet.

I have a young orchard to underdrain. With these facts before me, it would be useless to attempt it, unless I can hear where tiles are manufactured with collars, or to connect in some way to prevent one falling below the other, as I find the mice or moles have undermined mine.

I think, in laying a drain around a cellar, elbow tiles would be an advantage, as they require to be close to the wall.

What do you consider the best drain for a cellar? W. T. CROUCH.

Virgil, Jan. 31, 1870

Reply.—The roots look very much like grass roots; probably when the tiles were laid they were covered with turf—a very common practice, and the turf being put on with *roots downward* has caused the mischief. It is highly improbable that a tree in three years could shoot roots down into four feet of depth, when it was thirty feet away from the drain, however wet and soft the subsoil might be. The subsoil must evidently be soft sand (will Mr. Crouch inform us, and also say if the land was wet before it was drained?) which was wet and full of water before draining; in such cases there are frequently grasses that are called subaqueous, which cause a good deal of trouble to the drainer, often requiring a drain to be lifted and relaid after three years. The fault of the ten acre orchard seems to be the same as Mr. Coleman's, but we should like to know more about the condition of the land before draining, subsoil, fall, depth of drains and when laid, and distance apart. Tiles

being *undermined* is something new to us. In the absence of details. we can only say that a further knowledge will probably show that there has been shockingly bad work somewhere. Collars are not required except for wet sands. For the drainage of a house cellar, tight pipes are the best, with spigot and faucet joints, which ought to be rammed hard with strong clay. Elbows can be got for these. For other cellars, where there is plenty of fall for the water, tiles do very well with collars. They ought never to be laid *close* to a wall, but about three feet from it. Elbows are not made for tiles, nor are they required, as tiles can be laid to a small radius.—Ed.

Thistles.

To the Editor.

Sir,—I should like to say something encouraging for your correspondent "Enquirer," if possible. But unless he has overstated his weakness, or has represented himself as being more impatient of difficulties than he really is, I fear I shall not succeed. I have no new method of thistle-killing to suggest; but if I assure him that the old ones may be used effectually, and that he takes a mistaken view of the expense (arising, if he will forgive me for thinking so, from a limited apprehension of the science of agriculture), and then exhort him to firm resolve, patient perseverance, and methodical effort, I may perchance be so happy as to induce him to reconsider the following passages of his letter.

Says "Enquirer," "Recently I went to look at a very beautiful farm, but almost every field was badly infested with thistles;" and again, "If I cannot get a farm without thistles, I shall decline one at all, unless there is a less expensive way of dealing with them than the one 'Vectis' proposes."

My own feeling would be, if a very beautiful farm were offered to me, and I wanted to buy one, that its being infested with thistles would not, *alone*, be an obstacle to the purchase of it. For—assuming that the expression "very beautiful farm" means a farm with great natural advantages, and, perhaps, some other striking qualities—since I could destroy thistles by the ordinary methods of good tillage, but could not so readily find a substitute for natural goodness of quality, I should deem it wiser, on the whole, to buy the beautiful farm, thistles and all, than to trust to the precarious chances of finding *for sale* a good farm without thistles; for the men of Canada, so far as my observation goes, do not think it "smart" to sell farms of any sort while they are in good condition.

Your correspondent objects to "Vectis'" thorough summer fallow, on the score of expense, which he estimates at fifty dollars per ten acres, or five dollars per acre. Why, Sir, that farm which, whether be-thistled or not, is not made to undergo at stated periods some sort of effectual cleansing, must needs fall into very miserable plight, and it is to be feared that few of us can go far from our own homesteads without seeing various degrees of exemplifications of this necessity. Upon the choicest and cleanest land some such treatment is absolutely essential. It is everywhere admitted that these operations are the most expensive of all ordinary agricultural work, and for that reason they are, as we see, either altogether shirked, or very inadequately performed by not a few farmers. Hence, thistles and all the tribes of weeds. Hence, too, ten or fifteen bushels of spring wheat from land which would produce thirty or thirty-five, and twenty bushels of fall wheat from land which, even without general and thorough underdraining, would produce forty or forty-five bushels. In this fallow section of the Canadian farm really lies, after all, the true and most cogent reason why writers in the old country are able, when they have a purpose to serve by it, to almost ridicule our pretensions to living in a grain-growing country, and to speak with contempt of the outcome of our harvests.

The spirit of enterprise, which is not seldom disastrous in other departments of life, might with far greater safety be adopted by farmers who hug the present dollar, or put it out at usurious interest (itself a source of infinite mischief), and lead a dreary life upon their half-tilled farms, uncheered by those hopes of improvement which stir the minds and stimulate the energies of other men; while their sons, discouraged by the prospect, canter off to simper out their lives behind a counter, with a noble country like this around them. How different in England and Scotland, where, to become a farmer, like his father, is the ambition of nearly every boy reared on a farm; to whom an announcement on leaving school that he must now prepare to seek a livelihood in a city, is the shattering of dreams and hopes of entering upon a country life. Happy for Canada when so healthful an ambition shall take possession of her young sons. It is for their fathers to bring that state of things about; there is room for them at home.

SYSTEMATICALLY ENCOUNTERED.

Resuming the subject of the thistle difficulty, I now return to the letter of "Enquirer." Here we have a gentleman, whose letter gives evidence of a good education, hesitating to enter upon a "very beautiful farm,"—no, not hesitating—"declining" to take a good farm because of the thistles.

I am far from believing that bare fallowing is the most profitable treatment within reach, though it is the speediest as regards thistles, and involves the smallest present outlay. I only insist here that no farm can prosper without some such outlay, and that five dollars per acre, if it can be done for such a sum, is a mere bagatelle. I suppose the summer fallow to be, as is most convenient, the first step in a systematic rotation of five, six, or seven years; each crop in the course is supposed to, and really does, profit by it. Divide, then, five dollars by five, six, or seven or by whatever number of years may constitute your course, and see how insignificant is the charge per annum per acre, as compared with benefit accruing.

So much for the summer (or bare) fallow. But supposing that for a bare fallow hoed-crops of Indian corn and roots be substituted as the first member of the course. "Enquirer" would not be alone if he objected to this also, as being too expensive; yet, when all the charges upon a field of Indian corn and roots, thoroughly ploughed, hoed and manured, (considerable as those charges are), come to be apportioned amongst all the succeeding members of the rotation (as it is obvious they ought to be) who would not incur the outlay who had observed the wonderful renovation thus brought to the farm? Thoroughly ploughed and hoed, and well manured, the land must be, for upon these depend the force of the whole argument in favour of the plan, and eventual profit to the farmer. And this process, comparatively expensive though it be, apart from the destruction of thistles, apart from its effects upon succeeding crops, and regarded only as a means of making beef, mutton and pork for market, is a paying enterprise in the long run. Happily, at this day, the number of farmers following out such a system because they have proved it to be profitable, renders argument and demonstration unnecessary. Where it has long been well practised, their farms and their fortunes will demonstrate. Let the sceptics go see.

Under a judicious rotation and careful general culture, neither thistles nor other weeds have much chance of regaining their ascendancy between the periods of hoed crops or bare fallow, several opportunities occurring of disturbing them. We will suppose a hundred acres of land divided into six sections, for the purposes of rotation, and that the succession of crops is as follows:—

Section 1. Sixteen acres Indian corn, potatoes, turnips, bare fallow. As much of the land of this section as can be well manured to be under hoed crops. The unmanured remnant, if any, to be bare fallowed, and the absence of yard manure to be supplied, at the the earliest opportunity (which will occur at a subsequent stage of the course), by ploughing under a full crop of clover; unless sheep can be folded upon a crop of unmanured white turnips, or, still better, upon white turnips manured with bone dust, superphosphate, or guano.

Section 2. Sixteen acres wheat or barley, seeded with clover (thickly sown), and timothy or some other grass.

Section 3. Sixteen acres hay, which may be twice mowed if thistles abound, in which case the first mowing should be very early.

Section 4. Sixteen acres pasture. If the land be not very poor, a good crop of clover may still be expected here, which may be ploughed under on that part of the land which did not receive yard manure where fallowed.

Section 5. Sixteen acres peas and oats.

The pea land (and the oat land if both crops can be removed early), offers an opportunity of waging successful war with thistles, especially if the land be very dry, which is often the case, by immediate cross-ploughing and ridging up before winter.

Section 6. Sixteen acres wheat or barley.

It will be found convenient that these sections should adjoin each other as much as possible in the order of their numbers. Under this plan, or one akin to it, "Enquirer" might soon make havoc with the thistles which disturbed him so much, and would become practically convinced that the expense and trouble of the first section had been successfully applied with greater results than the mere destruction of thistles, and that the systematic operations through which they and all other weeds had received so great a shock, had also been the means of enriching his land, to say nothing of the simplification in the management of the farm thus introduced.

PRACTICALLY SUBDUED.

In illustration of the efficacy of the systematic course of culture recommended allow me to give the results of my own practical experience.

Seven years ago, at the age of fifty years, I gave up a business in the heart of a British city, and, with the slightest acquaintance with practical agriculture, came to this country and plunged forthwith *in medias res*, as a "book farmer." Since the first year, which was one of not much method, I have followed the course indicated in the former article as closely as the wretched circumstances of the farm would admit of; always, when I could not absolutely adhere to it, bending my arrangements towards it as a cherished object of full eventual attainment; and the amelioration thus effected may be indicated by a comparison of the former and present yields of the principal crops. My plans have again been much deranged by the purchase of an adjoining farm (grievously be-thistled), which I am bringing, bit by bit, under the rotation, along with the second course upon the old farm. The contrast of the two farms is painful to look upon, *mais nous changerons tout cela.*

	First Year.	1869.
Spring Wheat.	10 bushels.	26 bushels.
Barley.	24 "	50 "
Oats.	30 "	61 "
Peas	12 "	Destroyed by blight.
Turnips.	250 "	650 "
Indian Corn.		100 in cob.

A large portion of the wheat land produced this year over thirty bushels per acre. The oat crop was so heavy as to be all lodged, the yield being greatly diminished thereby, besides much waste in the field.

Of the clover, for want of an accurate estimate, I can only say that the first year's growth was ridiculously small, and that the quantity last year was exceedingly great. The above improvement has been brought about by one course only; the same treatment will, of course, continue effectual for many years, and may be rendered yet more so by thorough underdraining.

The tone of "Enquirer's" letter seems to indicate that he has been badly smitten with that spurious economy which prevails amongst us so largely, to the great injury of this country, and to which I have already alluded. It has had, as sickness will have, a depressing effect upon his nerves in view of minor difficulties. I must venture, however, to present to him one more draft upon his slender stock of faith in high farming. The best results cannot be reached (in the sense of profit) under the best scheme of tillage, unless all the Indian corn, oats, peas, hay, and roots are consumed upon the premises, or an equivalent be supplied by drawing manure from the towns, and the use of artificial manures. It is manure thus made that renders hoed crops profitable in fattening animals, and in the raising of grain crops. To sell them off the farm without an equivalent in return is really selling a part (the best part) of the farm.

I feel so much indebted to Stephen's "Book of the Farm" that I must, before I close this communication, very earnestly recommend it to all farmers. It may be got at Toronto. It is costly, but so it would be to open a gold mine. The most experienced farmer may read it with pleasure, and consult it with profit. The young farmer should devour it.

In conclusion, I will express my conviction, that generous and systematic treatment of land, a knowledge of principles, a courageous, persevering, energetic application of them, and capital, are essential to good and really profitable farming; that the more of these qualifications a man can bring to the work the less needs he to be frightened at thistles at starting, or to yield to misgivings about satisfactory pecuniary results; and that he who has them not in a fair degree should consider well before he commits his fortunes to the exhausted lands of the old clearings; for more or less exhausted or run out, and greatly out of condition, a large proportion of them are, especially when they come to be offered for sale.

BOOK FARMER.

Potato Produce.

Mr. Frederick Membery, of Bath, Ontario, sends us the following notes of his experience with a few varieties of potato during the past season. He says that with him the yield was as follows per acre:

Gleason.	600 bus.	No rot.
Cuzco.	630 "	One-third rotten.
Early Goodrich.	500 "	No rot.
Garnet Chili.	200 "	No rot.

Of the Early Goodrich the account was not so correctly kept as of the others, the potatoes being dug as they were required for use throughout the season. About seven pounds of Early Rose were planted, which yielded five bushels; none rotted.

Chemical Manures.

Some time since, we drew the attention of our readers to a series of experiments then progressing in France, which were intended to ascertain the relative value of chemical manures, as compared with the best barnyard or stable manure, not that it was intended either to deny or doubt the benefit to be derived from farm-yard or stable manures, but for the purpose of finding substances that might supplement and assist their action. In France, as in Canada, farm-yard manures are not produced in sufficient quantity to meet the requirements of the farm, and the originator of the system, a Mons. Geo. Ville, determined to go back to first principles, and see if he could not ascertain what the true source of fertility consists in. He therefore established a series of experiments, in which he at first made use of burnt sand, well leached and washed, so as to deprive it of every particle of natural fertility and vegetable organization, as his ground, and proceeded to use as his manures for that ground the pure mineral salts of lime, potash, soda, nitre, and the phosphates. These were reduced into a soluble state, and added to his burnt sand in various proportions, until he by almost innumerable experiments adduced the fact that grain and other crops of every kind could be produced in full perfection without one particle of earth or clay, or of natural manure or decaying vegetable matter, but with purely chemical elements alone. He proceeded with these experiments for many years, until he satisfied himself of the particular chemical substance wanted by each class of plants; and concluded, moreover, that while each class required certain quantities of all the above elements, they required especially a large portion of some one of those elements. He ascertained the exact amount each kind of crop would extract of these various chemical elements from the soil of an acre of land, and having ascertained the expense at which the chemical elements could be produced, he determined the cost and the profit of a crop so manured, as compared with a similar crop grown with ordinary manure. As no man with less than the fortune of a prince could afford the time and means to carry out such a series of experiments, it was made a national matter, and the funds requisite were supplied by the Emperor of the French. Meantime, the projector of these improvements made his plans known in a small treatise, most unfortunately entitled "High Farming without Manure," and he set forth the results of

his labours in such elaborate and high-flown language, as to elicit from many of those practical people who read the work unmitigated ridicule, while many were deterred from looking further than the title page and the first chapter or two, and then threw the book aside as altogether theoretical, and unworthy of attention. Those, however, who looked deeper into things, found amongst the verbiage of the work a great deal of valuable information and material for thought.

Mons. Ville, having the full support of the French Emperor, proceeded from his theoretical experiments to those of actual practice; he selected the poorest farm he could find, divided it off into sections, and having by analysis ascertained exactly of what the land consisted in its then present state, proceeded with his practical trials. One set of compartments he devoted to the successive cultivation (year after year) of one special sort of crop. Wheat followed wheat, barley followed barley, peas followed peas, and green crop followed green crop year after year, without rest or intermission. He now brought to bear the information he had acquired in his burnt sand, and added each year the general chemical manure, composed of all the before mentioned chemical substances, but only in so small a proportion as to produce the first growth of the crop, whilst in addition to the general manure, he added an increased quantity of the special element which the particular class of plants of which the growing crop consisted would abstract from the soil.

Thus, for his wheat and cereal crops he added to the soil, in addition to a certain quantity of general manure, a considerable portion of ammonia—ammonia and the various matters which produce it being the special manure for wheat and cereals generally.

To the land on which he sowed peas, beans, clover, etc., he gave the same proportion of the general manure, and in addition a quantity of potassa or potash—potash and its equivalents being the special manure for the pulse crop.

To the land on which he intended to raise roots he applied the same general manure, and in addition the phosphates—those and their producers being the special manure for all roots.

We are informed that, after a few years' experience, he could so exactly apportion his materials that he could take out a full crop of any particular kind, leaving the ground in so poor a state that without the annual addition it would not produce more than it would have done when he commenced to use it in its original state of poverty.

He also contended that by his system nothing was lost. If he applied a little too much of the general or of the special manure required for the use of the crop that year, it remained in the soil as available for the next year's crop.

As against this, however, must be taken into consideration the leaching away by the rains and natural waters of the soil of the excess of any mineral salt which had been added in so large a proportion as not to combine chemically with the elements of the soil. When combined, the roots of the plants alone could extract it. If in too great proportion, the roots of the plants seized on the overplus before they drew on the chemically combined elements of the soil, and thus is shown the importance of only adding to the soil soluble chemical manures in the spring and summer, while the roots are in full action, and can avail themselves of it; whereas the same soluble matter added in the winter season or in the fall passed off during the leaching of the winter's rains, and was lost to the agriculturist. On the other hand, chemical manures, not specially soluble, might be added to the soil at any time, and produce the proper effect in due season.

In addition to the before described compartments of the experimental farm, another set of compartments was applied to the production of the same kind of crop, sown and cultivated in the usual manner, but manured as before with chemical manures; and again other sets of compartments were applied to produce similar crops in a similar manner, but manured with barnyard and stable manure alone; and a last set of compartments was devoted to the production of unmanured crops, which only received assistance from the cultivation and moving of the soil in a state of nature, the use of the bare fallow, and the usual rotations, but always altogether without manure or stimulant of any kind.

This experimental farm was annually inspected by all the savans and acknowledged authorities on farming matters that could be got to look at it, and the results were carefully tabulated and noted in the records kept by Mons. Ville and his assistants.

The deductions drawn established, in Mons. Ville's estimation, the thorough triumph of the chemical manures over those of the barnyard or stable, and that to an extent of from thirty to fifty per cent., the cost of both kinds of manure being taken into consideration as well as the effect.

Not only was this advantage apparently secured, but the additional benefit was claimed that the chemically manured land not having the seeds of plants carried to the soil with the manure, became year after year more free from weeds and extraneous vegetation, while the land manured with ordinary stable and barnyard manure became foul with the weeds arising from the seeds returned to the soil in the manure, and which had not been destroyed by fermentation or moisture.

The latest recorded results are as follows:—

The experiments on wheat numbered 138, and the result in round numbers gave an advance of about nine bushels per acre in favour of the chemical manure, the cost of the chemical and of the natural farm manure being the same.

It was also found that a greater average of good crops annually was obtained from the chemical manure than from the other.

The experiments on potatoes produced similar results, also in favour of chemical manure.

83 experiments produced an average:

From chemical manure of nine tons, or 389 bushels per acre.

From farm-yard manure, 7 tons 7 cwt., or 317 bushels of potatoes per acre. (No doubt the French acre is here meant.)

From 160 experiments with beet root (sugar beet) the result gave an amount in favour of the chemical manure of within a few pounds of four tons per acre.

There are now experimental farms of this kind established all over France, in order to convince farmers by actual personal experience and inspection of the advantages to be gained by chemical and scientific knowledge, when applied to farming.

The results in the French colonies of similar operations, conducted on the same principles, have not been less conclusive. The owner of one of the best and largest plantations in Guadaloupe has found that the chemical manures possess the same advantages over ordinary manures in the growth of the sugar cane and other tropical crops that they do in France over ordinary crops—and it would be only multiplying instances to an unnecessary extent to adduce further results.

But it may be said by the Canadian farmer, "What is the use of all this to me? We cannot get chemical manures." In reply we say that information of what is going on in the rest of the world ought to be known to Canadian farmers as well as to every one else; that although we have not now chemical manures at hand, they are every day approaching us; that the lands all through the Southern States, which have been exhausted by slave labour and improvident farming, are now being daily renovated by these chemical manures; that immense manufactories of these manures are being established all over the States, and an immense amount of capital is being invested in them; that the use of such manures in Canada is inevitable in the course of a very short time, and that the minds of our farmers ought and must be prepared to receive the revolution in agriculture which the use of chemicals is certain to produce.

VECTIS.

Destroying Seedling Thistles

To the Editor.

Sir,—Permit me to make a few remarks on the "Note by Editor" to my previous article on the thistle in the February number of the Canada Farmer, where it is candidly admitted that the smothering system of "Publicola" may undoubtedly clear a field of *one* crop of thistles, (which is the only one thing up to the present that has been contended for), but what, it is asked, becomes of the countless myriads of seeds with which the soil is filled? a matter which has hitherto not been discussed. The destruction, or the subjugation, of the parent plant has been exclusively considered. Some even repudiated the idea of the thistle propagating itself by seed; but, happily, this strange notion no longer exists; for we are told in the "Note," countless myriads of seeds remain in the soil to germinate and fill the places of their exterminated parents, and then, "what is to prevent this?" This is a question I am anxious to answer. In the careful and pains-taking experiments recorded by "C" in the June number of 1869, page 204, he says the results of these experiments was "death, root and branch, but seedlings afterwards grew again from seed; but the first and second year they are easily destroyed." Now, had "C" stated how these seedlings are to be destroyed so easily at one and two years old, it would have met and answered the question propounded by Editor. "C" has undoubtedly given a latitude of one year too much for the seedling thistle to be "easily destroyed." A seedling thistle can be easily distinguished from the parent till after midsummer; but after the parent has been cut in the middle of July, or at harvest time, and has pushed up another vigorous bunch of leaves, then from this time the seedling takes rank with the parent, the one cannot be distinguished from the other, and the seedling of this year will surely mature its seed the next, but never in the first year. Thus to destroy them "easily" it must be done the first year, and it can be done as well as any other perennial.

Instead of allowing them after harvest to grow on unmolested to the end of the growing season and ripen all their leaves, before the middle of September the cultivator (not the plough) should be put over all stubbles infested with seedling thistles, and again before the middle of October; the second time it might be done a little deeper than the first. Care should be taken not to miss any portion of the ground. This process will not only destroy existing plants, but will excite the seeds of weeds that are on the surface to grow, which is equivalent to their destruction; whereas the plough would bury all such seeds where they would remain in a state of perfect preservation till they were again brought to the surface. To go over stubbles infested with thistles with the cultivator twice will only take half as much time as it would to plough it, and is practicable for all; and after the thistles have had a second growth after harvest, to be thus cut off twice in the fall will be found far more efficient in the destruction of even the parent plant than ploughing, or even such fallowing as the majority of farmers can afford to give. Twenty years ago I have destroyed long established patches of thistles on pasture land, without ever disturbing a root, only by mowing the tops off, and never suffering them to ripen or mature in the fall. I have also killed out the most obstinate patches of couch grass without disturbing the roots, with only occasional hoeings, so that the tops were never allowed to mature.

Settling in this locality, where thistle growing is a rule in all fields, and if there are exceptions they are unknown to me, and my own land being well supplied, I resolved as soon as I could to try the clover system, and this county being pre-eminently suited for the growth of clover, I felt no demurring about the result. A hundred years ago it was as great a nuisance in England as it is here; but the plan they adopted was just the opposite of that which is here in Canada insisted on. In *Loudon's Encyclopædia* I find it stated that "the thistle delights to grow in ploughed fields," and instead of fallowing for its subjugation, English farmers seeded the infested fields down into meadows, and so left them for seven years to accomplish that which they as utterly failed to do with the plough as the Canadians do at this day. I would here remark that the thistle cannot increase, or propagate itself, on clover leys or meadows. The seeds that might lodge, or even vegetate in spring, would surely come to nought. It might just as well germinate in a wooden box with the lid on; for without light and air the young plant must die, and in neither of the foregoing cases could it obtain that light and air.

I would challenge any farmer in Canada, to say, or prove, when he laid down a field in pasture, and such pasture should have just two small patches in thistles and no more, that at the end of seven years he had three patches, or even two large ones. Apart from the consideration of the seedling thistle, the plough has been, and is, the most perfect instrument to propagate the old plant by the roots. In ploughing stubbles or meadows late in the fall, with an abundance of well matured thistle heads, they come in contact with the opposite slice as the mould-board twists them over, and their heads get bent upwards, and a large portion of their upturned roots, just covered with earth, are in the best possible position to throw up several new shoots from the otherwise latent buds. The land so ploughed late in the fall is often in the best possible condition to sow in the spring without further ploughing, and the result is, a double number of parent thistles, to say nothing about seedlings; and hence, ploughing is the only one efficient method to practical farmers for the successful propagation of the Canada thistle.

I contend that the complete subjugation of this pest by the fallow system is impracticable. It is an old saying as well as true, that "one year's seeding makes seven year's weeding," and it is saying too much on behalf of *one* year's fallowing that all the seeds of any one plant weed can all be brought to the surface and be excited to growth,—even if the farmer could plough his fallow for twenty consecutive weeks; therefore, I fail to see how the evil is combated and exterminated by one year's fallowing. I contend further that the admissions of those who advocate the fallow system prove its inefficiency. "C," in the article to which I have already alluded, says, and very truly, "we know that fallowing in dry, hot weather will kill thousands of thistles, but some few old roots remain uninjured, any quantity of seed also remains ready to sprout and grow on being exposed to the air." So that his notion of fallowing did not combat with the seedlings, "the source of the evil." His plan of ploughing the thistles in the middle of June, and then to keep combatting them to the end of the growing season (say four months) is a very serious affair, and not one farmer in ten will, or can, attend to it as prescribed; and if any of the thistles escape, all the labour (or most of it) is lost for that year.

In place of the foregoing expensive remedies, and their more than doubtful success, as proved to demonstration by the advocates themselves, I offer the clover system, which involves no trouble, no loss, nor any doubt in its results, and have answered to the best of my abilities the new element introduced into this discussion, by the query respecting the seedling. In answer to this, I propose that the cultivator be used twice in the fall, instead of ploughing in; after which it is beneficial to plough the land, and this system should be continued so long as the prevailing thistle scourge remains. Without deranging his operations (if he willed it) the farmer could walk over his hundred acres, in five years, with the clover system, when not a seed-bearing thistle would be found in his once disfigured fields; then as to the seedlings, they are, (as "C" remarks) easily destroyed the first, but not the second, year.

PUBLICOLA.

Arnold's Hybrid Wheat.

A limited quantity of these new varieties of wheat, the results of Mr. C. Arnold's carefully conducted hybridizing experiments, will probably be in the market after next season's crop, and we have pleasure in publishing extracts from the report of the Committee appointed by the Board of Agriculture to examine the wheat. The Committee consisted of Hon. D. Christie, Messrs. W. H. Mills and James Cowan, who state that in their opinion the wheats were "really new varieties—cross-bred, and inheriting some of the valuable qualities of both parents; that is, they seemed to have the midge-proof character of the Amber Michigan, while Soules parentage had greatly improved the quality of the grain as compared with that of the Amber Michigan. Another important fact ought to be stated, viz.; the ears of the new varieties were much larger than those of the parent kinds, while they had even more than the compactness of the Soules wheat. The yield per acre was large, being as Mr. Arnold says, 52 bushels per acre. This return was not the result of extra culture; the land was not better prepared than any good farmer would deem necessary for good crops."

A Committee appointed by the North Brant Agricultural Society to examine these varieties of wheat report in similar favourable terms, respecting the size of the berry, the productiveness, hardiness, and midge-proof qualities of the grain. Many other agricultural authorities have given equally flattering testimony, and we shall watch the result of more extended trial with much interest. Such experiments as those of Mr. Arnold deserve every encouragement, and in the present aspect of the wheat question, and considering the gradual deterioration of most of the old varieties, the matter is of special importance.

Sugar-Beet Contrasted with Mangold.

Sugar-beet is being extensively cultivated in Great Britain as food for stock, and for this purpose it is fast coming into competition with mangold. A correspondent of the *Agricultural Gazette* says that, as a rule, the sugar-beet does not grow as large as the mangold, and therefore to ensure the same weight per acre more must be grown. To make this plain, he presumes that in an ordinary crop of large mangold there will be from sixty to eighty roots to the perch. Now, in sugar-beets there should be about two hundred roots to the same area. This increase of the individual roots will compensate for their lightness, and the gross yield of the sugar-beet will probably be as great as that of mangold. Already they are running each other pretty close in the Lavenham district. The heaviest crop of sugar-beet this year weighed in the gross thirty-one tons per acre The best crop of mangolds weighed one ton less, or thirty tons per acre. Weighed without tops the mangolds reached twenty four tons per acre, and the sugar-beets twenty one and a half tons. The number of mangolds per perch was one hundred; of sugar-beets, two hundred.

These facts and figures point a lesson and indicate the direction improvement should take in regard to sugar-beet. Many a one who remembers the first crop mangolds, with their uncouth roots and coarse large leaves, and contrasts them with the fine stock and small leaves of the most approved sorts of to-day, will see, at a glance, that the same course of selection and crossing, if needful, must be pursued with the sugar-beet. Among the crops now there are great differences in regard to top and habit. These have been noted by the growers, and most of them are saving their own seed from what they consider the best samples. It is probable that in a few years there will be model crops of sugar-beet, with little, if any, greater development of top than among the best mangolds Once this is accomplished, the roots may go even closer together, and as, bulk for bulk, they weigh heavier than common mangold, it follows that by-and-by we shall have as heavy, or even heavier, crops of the sugar-beet per acre.

Selecting Seed.

We cannot too strongly urge upon the farmers the importance of exercising a close supervision in selecting samples of seed, especially grain, of whatever crop is intended to be grown.

In the first place, it should be sound, plump and solid, and of the most productive varieties; and in the second, it should be entirely pure and free from any admixture of other grain of the same kind, and the seeds of weeds.

We are no advocate of the plan followed by some, of giving extortionate prices for a fancy article, with some new-fangled name, the merits of which are belauded in highly coloured circulars and advertisements of interested dealers. We believe good seed can be had at reasonable prices from those who, by careful selection, and clean culture, find it pay to dispose of their produce for seeding purposes, and having acquired a good name by honest dealing, are anxious to keep it up.

Above all, use the fanning mill; it is not valued half as much as it should be, and even with the best of seed we would run grain through at least once before sowing.

PRIZE ESSAY.—We have received a copy of an essay on turnip culture, by H. Love, Secretary of the South Huron Agricultural Society. This excellent treatise received, at the last fall show of the Society, the prize offered by the President, Mr. Dickson, for the best essay on the subject, and the author has well merited the honour. The essay is thoroughly practical, and its publication will no doubt promote the interests of agriculture in the county.

Stock Department.

Notes on Canadian Herds.

No. VIII.

About ten miles north of Duffin's Creek station, G.T.R., near Atha P.O., Pickering township, is Burnside Farm, the residence of John M. Bell, Esq., comprising some 200 acres. He commenced his herd of Shorthorns in 1857, with two cows imported from Scotland, along with some of George Miller's, brought out at the same time. They were Jane 3rd, by Sir John (13735), from Young Jane by Strathmore (6547), and Lucy Neal, by Sir Charles (13705), from Young Rose, by Remus (11987), both bred by Robert Syme, of Redkirk. In our account of George Miller's herd, these two were erroneously credited to him. Jane 3rd has gone to the butcher long ago, and left but one female descendant, Jane 4th. Lucy Neal, a fine rich roan cow, still survives, and stands at the head of the herd. She is now in her 15th year, and is a large massive animal of great depth and substance, and has bred regularly up to the present time. Jane 4th, a light roan cow fourteen years old, by Nichol [497], is a fine milker. She has a neat red heifer calf, Ruby, by Highland Chief. Jessie, roan, nine years, is by Young England [822] from Lucy Neal. She is a fine cow, though not so massive as her dam, and has a very handsome red and white heifer calf, Favourite, by Highland Chief. Jane 5th, roan, nine years, by Prince of Wales [578] from Jane 4th, is of good quality and a splendid milker. She has a heifer calf by Highland Chief. Bride, roan, six years, by Charles [118] from Jane 4th, is much of the same style. She has a red bull calf by Highland Chief. Bessie Bell 3rd, red with some white, 5 years, by Clifton Duke 2nd, [133] from Bessie Bell, is one of the best in the herd. She partakes strongly of the Kentucky character through her sire. Mary Gray, roan, five years, by Prior [589] from Jane 5th, partakes of the good milking quality of her dam, while she has good style and substance from her sire. She has a red bull calf, Redcap, by Highland Chief. Jane 6th, red, four years, is by Prior from Jane 5th. She is rather small, though of good style and quality. She has a very fine red bull calf, Grand Duke, by Highland Chief. Pride, white, three years, by Prior from Jessie, is the handsomest animal in the herd, and for her age is very large and massive. She has a roan bull calf, six months old, Comet, by Highland Chief, and though milking well, is in high condition, and a better representative of the breed, combining size, quality, and style, is not often seen. Tulip, dark roan, two years, by Prior, from Bride, is a large handsome heifer, of good substance. Empress, red roan, fifteen months, by Oxford Mazurka, from Mary Gray, is a beautiful animal of great size for her age, yet neat and handsome. She looks the best of the young ones, and is a credit to her sire. Jessie 2nd, red roan, four years, by Prior from Jessie, is a long-bodied neat cow. Snowdrop, white, four years, by Prior from Jane 4th, is in thin condition from a recent illness, and does not show to advantage, though of high quality. Melody, roan, three years, by Prior from Jane 4th, though somewhat small, is a fine, handsome, neat animal. Rose, red and white, by Valentine from Jessie 2nd, is inferior in quality to the rest of the herd. Miss Ann, roan, two years, by Prior from Jessie, is a large and somewhat coarse animal, that may improve with age. Flattery, white, two years, by Prior from Jane 5th, is promising, though small yet. Daisy, roan, one year, by Highland Chief from Snowdrop, is a very promising young one, as is also Jenny Lind, a roan yearling, by the same bull, from Jessie 2nd.

The bull now in use is Highland Chief, 6884, a dark red bull of fine style and good substance, bred by J. M. Hill, of Harristown, Ill, U. S. He is by 11th Duke of Airdrie, 5533, from Margery by Afton, 1173. He is now three years of age, was imported by Mr. W. Miller, jr., of Pickering, and sold to Mr. Bell early in the fall of 1868. Previous to this Prior, [589] a roan bull bred by R. A. Alexander, of Kentucky, had been used by Mr. Bell. He was by The Priest [743] from Fanny by Fantichini (12862), and traces back through his sire to Earl of Dublin (10178), a bull of the best milking strain of shorthorns in England. The introduction of these two Kentucky bulls into the herd seems to have been the means of improving it greatly, and taking the whole herd together, it is seldom one meets with one of more level and evenly good quality throughout, combining both size and style with good milking properties.

The stock get no feeding beyond hay and turnips, are kept in good breeding condition, and have never yet been shown at Provincial Exhibitions, but will be this year.

A few Cotswold and Leicester sheep are kept on the farm, and several Clydesdale colts were running in the straw-yard.

While in Markham, we did not forget to call on George Miller, the patriarch breeder of shorthorns in Canada. The young ones we saw last fall are in fine thrifty condition, looking most beautiful. Already this season's calves by Bell Duke of Oxford have begun to come in, and present indications show the likelihood of another splendid lot of shorthorns by him.

Mr. Miller showed us a very fine Berkshire sow he has lately obtained from Mr. H. Cochrane, and some Dorking fowls just out from Scotland. He has sent two of his finest heifers by Bell Duke, to 11th Duke of Thorndale, at Compton.

The American Short-horn Herd Book.

The ninth volume of this important work, indispensable to the short-horn breeder of the neighbouring States, and exceedingly useful to many in Canada, has just been issued by the well-known editor and publisher, Lewis F. Allen, of Buffalo, N.Y., price $10. It is handsomely got up, and bound in cloth, in two parts, containing together over 1,000 pages. Part I. contains the pedigrees of 1959 bulls, from 7439 to 9398. Part II. has the pedigrees of about 3,520 cows, making altogether in the volume some 5,380.

The accumulation of so large a number of pedigrees for publication in so short a time, Vol. VIII. having been published scarcely two years back, affords pretty strong proof of the activity prevailing at present in the pursuit of short-horn breeding in the adjoining States of the Union. And there appears very good reason too for such activity, if we may judge from the highly remunerative prices at which high-bred short-horns have been sold in numerous instances of late. Mr. Allen in his preface says:—

"Prices for choice animals were never so high, nor were such animals ever so eagerly sought by our enterprising farmers and breeders as during the past two years. Some bulls and cows have been imported from England during the past year at a cost varying from $2,000 to $5,000 each, in gold coin. Several cows, of American breeding, have been sold in our own State, at $3,000 to $7,000 each, and bulls at $1,500 to $6,000 each. Concurrent with their progress here, short-horns never sold at such high prices in England as now, nor need these be considered FANCY prices alone. Fashion, no doubt, to some extent prevails in the choice of some peculiar strains of blood and styles of form; but when the prices we have named are paid by experienced breeders, and those among the best judges of quality and blood in cattle, it may well be believed that they find their interest in so doing. Men of education, wide intelligence and ample capital, in all our Northern and Middle States, engaged in various pursuits other than agriculture, are among our most enterprising cattle breeders, as well as those whose vocation is confined to their farms alone, and in this noble pursuit they find both profit and pleasure. More and better than this, every good cattle breeder in the country is a public benefactor."

Vol. IX. contains an unusually large number of illustrations, about seventy, several of them being portraits of animals which have recently changed hands at very high figures. We need only call the attention of breeders to the fact of the publication of the volume to ensure a ready demand for it among those interested.

The Barmpton Short-horns.

Even at this distant day, a short account of the celebrated herd of Robert Colling, the descendants of which are now so widely scattered wherever short-horns are known, will be interesting.

In 1783, Robert Colling left his brother and took the Barmpton farm. Some of his earliest stock came from Mr. Milbank of Barmingham. These were noted for their excellent grazing properties.

From one of the original cows of this stock came the Yellow Cow, by Punch (531); from her came by Favourite (252) the dam of the celebrated "White Heifer that travelled." She was twin with White Bull (151), and never bred. From the Yellow Cow came North Star (459), also by Favourite. He was a grand bull, with good hair and fine handling. From her came the cows Venus and Clara, and Diamond, a small bull of perfect symmetry. Venus bred the bull Adonis (7), and a heifer that was sold young. Clara bred the bull Eryholme (1018) and another bull and heifer.

Robert Colling had four families from which the majority of his stock descended. Of these the Yellow Cow above mentioned was one. The second was the Wildair or Hubback tribe, which came from the same source as Hubback (319). Of these were Juno, Diana, Wildair, and Nonpareil, the last considered the finest cow ever seen. Nonpareil bred Sweetbriar, by North Star (459), and Marske

(418) a bull used by Mr. Bates. Sweetbriar bred May Rose, that went to Ireland, and Formosa, that bred Mr. Torr's Flora, from which the Flower tribe, the finest at Aylesby, have descended. Wildair bred Caroline, Harold (291), Phœnix, Emperor (1013) and three other bulls. Phœnix went to Charles Colling, of Ketton, and there bred the celebrated bull Comet (155), sold for a thousand guineas. The third was the Beauty, or Punch tribe, originally from Mr. Best, of Manfield. Of this were Beauty, Golden Pippin, Clarissa and Old Daisy. Beauty was from the same dam as Punch (531). Golden Pippin was by North Star, and went to Mr. Whitaker, where she bred Nonsuch, and both then went to Mr. Adkins, of Milcote. Old Daisy bred Ben (70) and Twin Brother to Ben (660) afterwards sold to Mr. Booth. The fourth was the Red or Moss Rose tribe, of which the origin is unknown. Red Rose was own sister to the American Cow, the first female named in the now fashionable Cambridge Rose line. This cow was bred by Robert Colling, and sold by him when a yearling, to go to America. She came back again, and passed into the hands of Mr. Bates when 17 years old, and bred Red Rose 1st, by Yarborough. Red Rose bred Moss Rose by her own sire, and proved a regular and excellent breeder, most of her calves being bulls. Among them were Miner (441), Midas (435) a fine large bull that made 1,100 guineas for Mr. Colling, and finally went to Mr. Wiley, of Brandsby, and got for him but two calves, Midas, 1230, and the famous Grazier (1085). She also bred Baronet (62), sold for 350 guineas, and Pilot, (496), sold to Mr. Booth for 270 guineas, and a heifer Rosette. Moss Rose bred Barmpton (54), Lancaster (360), and Young Moss Rose. Barmpton was a small-aized but beautiful roan, neat, wide backed and compact. He got splendid stock, said to be better than North Star's. He was by George (275), a magnificent bull that fell and broke his neck when young. Lancaster, a white bull, was of fine quality, but narrow, thin, small and lanky. He was let cheap as a yearling, but got most extraordinarily good stock, that became the talk of the country. This, coupled with the fact of his being from so grand a cow, brought Mr. Colling 621 guineas for him. Young Moss Rose went to Stockeld Park, where her descendants still remain.

Besides these leading families, Mr. R. Colling had several heifers got by Favourite (252) and Wellington (680), from cows bought from his neighbours or at the fairs, most of which became progenitors of many fine short-horn families. Among them may he noted Cowslip, from which came the Ursula tribe of Mr. Rich of Didmarton, Empress, Princess—from which came the Gwynne tribe—Strawberry—from which came the Mantilini tribe—Jessy and Jewel (twins), Cicely, White Rose, Lady, Old Dinsdale, Countess, and Young Charlotte, besides several others, some not named.

Hubback (319) and Manfield (404) were the first bulls used, succeeded by Broken Horn (95), Punch (531), Favourite (252), Comet (155), Phenomenon (491), Wellington 680, besides several bulls of his own breeding, as he bred to very close affinities, using Favourite very extensively for years.

At the sale at Barmpton, in 1818, eleven of the Red Rose tribe, including Lancaster (360), brought an average of £269 3s. 6d. each, and thirteen of the Wildair tribe £142 17s. 6d. each.

Housing and Feeding Cattle

To the Editor.

Sir,—Having seen in the Canada Farmer some articles about housing and feeding cattle, and believing that in some particulars I can suggest improvements, I send you an account of my operations.

For the accommodation of my cows I raised a house, sixty-four by thirty-four feet within, in the side of a clay bank. There is a cellar of stone and lime, eight and a half feet high, divided by a wall across, fifteen feet from one end, so as to make a cellar for roots. It is ventilated by four pipes on three sides, six by six inches, through the floor and walls, with slides to cover them. The floor is drained into a well of good sweet water. There is a ring of brick laid in cement round the well. The spare water is let out through a pipe. The floor is laid with cement. The floor of the large cellar is also well drained and laid with cement; and besides, about two and a half feet of the walls are cemented to keep bad water from the well. There are four stone pillars and two cedar posts in the cellar to support the floor above, and the purlin posts. The door for taking out the manure is level with the floor. There is no frost in the manure. The cellar will hold five or six months' manure; and the small cellar will hold roots to supply twenty-eight cows all the season, at the rate of twenty pounds daily each. The beams for the first floor are cedar, resting on the walls, and on the pillars mentioned as being in the cellar. There is some care needed in placing these beams to answer the different inclines of the cattle floor. The floor is of two inch pine. There are four rows of cows, seven in each. There is a passage the length of the house. There are two doors in the side. Fourteen cows go in at each door, and stand with their tails to each other. The upright scantlings that form the stalls are fastened to the floor below and the beams above. The feeding troughs are made, the bottoms of two inch pine and sides of one and a half inch pine; the divisions between them being four and a half feet high; the inside of the feeding box is sixteen inches wide, the front eight inches high, the back thirty-one inches above the bottom. The back of the box inclines outward seven inches; this is important, as it prevents the beast wasting the food. There are pieces of three or four inch scantling put between the floor and the bottom of the box. The distance between the front of the feeding box and the gutter may be six feet; the two gutters, with the open space between them of fifteen inches, will be three feet eight inches. The gutters are two inches below the floor; where the cow stands pieces of three inch scantling are put across the open space of fifteen inches, and a two inch plank, twenty-two inches wide, covers it; all excrements pass into the cellar below this plank. There is no trouble to keep the cows dry and clean, and no waste of manure; there is no excess of water in winter. Some black earth or dry earth, not much, is wanted in summer to absorb the excess of water. There are five windows in the back of the house, and three in the front, with the two doors. There are six openings, thirteen by fourteen inches, through the upper floor, and pipes set on them that reach up through the hay. In the roof there are two windows and two ventilators, which draw off all smell or bad air, and in addition, there is a window high up in each gable. The windows are all alike, six lights, eight by ten, and boards, ten by twelve, on hinges. The house is a frame, with cedar sills, the posts being eight by eight inches, and sixteen feet high; covered with good boards—the joints covered with dressed stuff, one inch by three, nailed every two feet. It is lined inside with inch boards, and filled in with tanners' bark. The floor above for hay is eight and a half feet to the roof, and thirteen and a half feet to the purlin beams; it will hold hay for the twenty-eight cows. The roof got two coats of coal tar; and the siding two coats of fire-proof paint. Hay may be taken in at either end with a horse-fork. There is a space above the turnip cellar, fourteen by thirty-three feet, for preparing food; in it there is a pump, a turnip-cutter, a bin for holding broken grain, and three boxes, five feet by seven and four feet deep, to hold the food.

After a good deal of experience, and some study and calculation, I have come to the conclusion that the following quantities and mixture of food are about right for a fair-sized cow giving milk: Twenty pounds clover hay, twenty pounds turnips or beets (fine cut), two pounds bran, five pounds broken oats, two pounds pea-meal (equal altogether to 45 pounds hay). Some small cow will eat less, and large ones more. The mixed food being placed in the box, put in

the same amount for every cow: the box will hold feed for thirty cows. Damp it well with water, and tread it down, in forty-eight hours it will ferment and be hot; then feed out. I use a barrow with two wheels that holds twenty bushels; the man draws it easily along, and with a bushel box divides it in a few minutes. If any cow wants more, give a little dry hay, and as much water as she will drink, three times daily. I, for some years, fed about sixty pounds Swedish turnips, five pounds meal, pea and oat, with fifteen pounds hay. Steers or dry cows would not take any water; the bulk is too much, and there is too much cold water in the turnips. This is about equal to thirty-nine pounds hay. There is one hundred pounds oil-cake wanted (it costs delivered three-quarters of a cent per pound), two pounds daily three or four weeks before calving, and two pounds daily a month after calving, when full feed should be given, as described above, until cut grass is plenty.

I am satisfied with the method, having used it nearly four months. The rent for each cow, at ten per cent., is four dollars per annum. This may be high, but the convenience is all one can desire. The house is free from smell, well lighted, and has water and room for the roots and hay to feed the winter through. The cellars cost near twenty-five per cent. of the whole. There is a hay-cutter on the upper floor; the cut hay is let down through the floor into the large boxes; it just wants a steam-engine to crush 2,500 bushels of grain and cut 140 tons of hay, with straw for litter. If all litter were cut, the manure could be taken out and spread on the surface of the field, or ploughed in, as might be desired. My other cow-house holds thirty cows, but is not so convenient; but I hope to improve it soon.

JOHN ROBERTSON.

Bell's Corners.

Live Stock at the Provincial Exhibition

To the Editor.

Sir,—With your permission I desire to call the attention of the members of the Council of the Provincial Agricultural Association to a few matters in connection with the annual exhibitions of the Association, which I think deserve their consideration. Probably no one will deny that the live stock department is one of the most important features, if not the most important, in connection with these exhibitions. Let our Provincial Fairs be stripped of the fine display of horses, cattle, sheep, and swine, which has made them so justly famous, and who will deny that their greatest attraction would be gone. It is safe to say that the interest taken in them would be small compared with what it is, and the attendance of visitors would be correspondingly reduced. Now, I think a little consideration will suffice to show that it is the worst used department in the whole exhibition. For the reception of the articles exhibited in the other departments a grand building is erected at an immense expense, where those articles are exhibited to great advantage, and men are paid to take care of them, and all this without the first shilling of expense to the exhibitor; while for the live stock, which is infinitely more valuable and just as liable to suffer from exposure, temporary sheds are provided, which are often uncomfortable and inadequate; and if a box stall is required for a horse or a bull, an exorbitant rent fee is charged.

Besides these things, feed is only provided at extortionate prices, often for an inferior article, and parties are not allowed to sell feed on the ground at their own prices, because the Board has granted that special privilege to special parties, who are allowed to monopolize the business. How very different is this from the arrangements at the State Fairs of our neighbours, where an abundance of good hay is provided by the Association for the stock, without any charge; where stalls are free, and railway freights both to and from the fairs are also free. If this interest is so important, surely it ought to be encouraged. I write not in the interest of the leading breeders and exhibitors alone, for I know that they can afford to pay their own expenses, that by showing a large number of things they can secure enough prize money to pay the immediate expense of attending the fair, besides finding a good market for their stock; but I plead in the interest of the new beginners in this enterprise, and I hold that if greater encouragement were given there would be far more exhibitors, and, consequently, more interest manifested. According to the present arrangement, if a person living a considerable distance from the place where the fair is held desires to show a horse or a bull, he finds that if he is successful in winning a first prize, it will barely pay the expenses of transportation and feed, and if he fails to win a prize the whole expense is lost to him, and thus it is that many are deterred from competing. The expense of preparing stock for exhibition is considerable, and the railway charges for transportation are also heavy, to say nothing of the risk of their being injured or killed.

Why cannot the same arrangement be made with our railways that are made by the State Societies across the lines with their railways? Canadians who take stock to the State Fairs can travel by rail with their stock to almost any point and return, free of all charges. Surely the immense extra passenger traffic which these events bring to the railways is sufficient to pay for the carrying of articles to and from the exhibition, and allow a good margin for profit. When we consider that it is these that make up our fairs and draw the crowds, surely some liberal policy ought to be adopted to draw out our young farmers and breeders. I claim that in all fairness and reason stock ought to be carried to and from the fairs free, and that stalls and hay ought to be provided free. All, I believe, even if they do not claim as much as I do, will agree with me that ample and good accomodation, and food at a low rate, should be provided.

YOUNG FARMER.

Raising Calves.

To the Editor.

Sir,—In your article under the above heading, which appears in your issue of the 4th inst, I agree with the introductory portion, but must take exception to your directions for feeding and care when approaching maturity:—

1. In advising to give skimmed milk, and afterwards either that or sour milk mixed with meal.

2. In having them *come in* as cows in their third year.

When skimmed milk is given to a calf, it acts as a purgative, which at once sickens the animal, and causes it to refuse food for two days, and for a long time every dose of this unnatural food is followed with like results.

A continual drenching of the calf retards its growth at the outset, and an inferior animal is to be expected. The addition of the meal only increases the indigestibility of the mixture.

I have been for several years in the employ of noted stock raisers in Scotland, and their system was to allow the calves selected for raising to suck the mothers twice a day (they being separated the rest of the time). This was continued till they were six months old. After each removal of the calf, the cows were carefully examined to see that no milk was left, and if any, it was taken from them.

During the summer, the calves were placed in a field of growing grass or clover, and freely supplied with water. Nothing else was given.

When weaned, and during the cold weather, they should be provided with a warm stable, and regularly fed three times a day with good hay; every morning the rack to be cleaned before being supplied with fresh hay. About a pailful of dry provender to four calves to be given every twenty-four hours, or as an occasional substitute, two sheaves of oats.

During wet and stormy weather, they should be watered in the stable. It is not good policy to allow lambs to be with them as you advise, as calves often get into the habit of eating the wool of these, which would be obviated by separation. During the second winter it is still advisable to keep them separate from the older cattle, while they should be housed and liberally fed. By this method the growth is never checked nor retarded, and if it were followed we should not have so many scrubby specimens of cows in the country.

Again, you defeat your object to secure good cows by allowing them to go to the bull so early as to have them *come in* in their third year.

The growth is not completed till the third year, and it is mistaken policy to have them bear and give milk before their fourth year, or till they have arrived at maturity. This, with the skimmed milk course, is in my opinion the great cause of our inferior stock.

Our winters here are more favourable for cattle raising, when they are properly fed and sheltered, than the changeable winters of Scotland, and if they get the justice there given them, we should have at least equal if not superior animals.

MALCOLM McGREGOR,
Roxborough, Feb. 24, 1870.

NOTE BY ED.—Our article on this subject was not intended to apply to the case of breeders of high class thoroughbred shorthorns, or in cases where the value of the milk is a secondary consideration to the value of the animal intended to be raised in order to fetch a fancy price. In their cases it is quite usual to allow the calves to suck the cows, or even where that course is not pursued (and it is a most undesirable one in many respects), they are allowed nothing but new milk. But it would be folly to expect the farmers, as a class, to devote all the new milk of their cows to the sole purpose of raising calves, when it is worth more for making butter. As to skimmed milk being continually purgative, our own experience, as well as that of several other breeders to whom we have lately spoken with reference to this subject, is that it is not so. If given to a calf accustomed to suck, or have new milk warm from the cow, it would in many cases prove purgative for the first two or three days. We have found that if warmed to a proper degree it does not purge to any appreciable extent. The meal should be boiled, and then stirred in; but then few will take that trouble, and we fear few even take the trouble to heat their skimmed milk to a proper degree, and it is giving the calf the milk cold that causes all the trouble our correspondent speaks of.

In regard to the other point, opinions may well be allowed to differ; but our object was to show that animals that had been well fed and cared for would attain maturity, and so be fit to breed, earlier than those that were neglected and stunted. A few days since we saw a very fine shorthorn cow, now six years old, that has bred six calves at single births, the first one coming when she was eighteen months old; and we think few breeders of pure stock in this country could be satisfied to wait for their heifers to reach their fourth year before breeding.

Shrinkage on Hogs.

We have as yet received but very few answers to our enquiries on this subject. The cause may lie in the lateness of the season at which they were made, the greater portion of the hog products having probably been marketed. Another is the difficulty experienced by farmers in getting fat hogs correctly weighed at just the right time.

A firm in Pennsylvania, largely engaged in fatting hogs of the Chester White breed, gives the shrinkage or loss between live and dressed weight of a large number as follows: On hogs weighing over 600 pounds, loss 12 pounds per 100 of live weight, or less than one-eighth. 300 to 600 pounds, 14 pounds per 100, or less than one-seventh; 150 to 300 pounds, 16 pounds per 100, or less than one-sixth.

They say common scrub hogs will lose more, and that there is a wide margin for profit between feeding improved breeds and common hogs, more than sufficient to pay the extra prices demanded for animals of the former.

A Mr. Eckardt, of Markham, gives the live weights of two eight months old Berkshires he killed as 302 and 283 pounds respectively. Each gave twelve pounds of rough lard, and weighed besides 250 and 245 pounds, showing a loss of less than one-tenth. Another Pennsylvanian gives an account of a Chester White hog he killed that weighed 1,065 pounds alive, and 1,005 pounds dressed; less than one-sixteenth of loss. An Ohio man gives the live weight of a twenty-three months old Chester hog at 985 pounds; dressed weight 870 pounds, a loss of one-ninth.

We hope to get some more answers, and shall reserve any further remarks on the subject till it can be more fully investigated, but so far the evidence is in favour of what we have always maintained, viz., that the amount of shrinkage insisted upon by drovers and packers in buying fat hogs alive is much too great for the interests of the farmer who has really good hogs to sell.

Barren Cows or Heifers

It is no unfrequent cause of complaint with breeders that valuable cows or heifers sometimes fail to breed. Such instances rarely occur, except in the cases of animals that have been pampered, that is, brought to a high condition by means of extra feeding or "forcing," as it is called. Such animals need not be condemned as barren, as under good management they can be brought to breed. It is well to reduce them in flesh about the beginning of summer, by turning them into a hilly short pasturage for a time. A long drive will often prove beneficial. Sometimes a change from one herd or farm to another some miles away proves a sure remedy after every other has failed.

Deliosacy of constitution may sometimes be the cause, from too close in and in breeding, and where the same bull has been used in a herd for some years he may fail with some of the younger cows and heifers, in which cases resort must be had to another bull that is in no way related to the herd.

Bulls that are too closely bred, or that are fed too much on rich carbonaceous food, frequently prove unreliable stock getters. They should get albuminous food in preference, such as peas, oats, barley, and the leguminous grasses. In fact, anything very saccharine or sweet is undesirable. A bull should always be kept in good condition, but should not get fat, and the more he is used the more need there is of giving him oats or barley, but he should never have Indian corn. The forcing of bulls when young, in order to get them into high condition and early use, is sure to prove injurious, and result in greatly diminishing their vigour. Neglect to give salt at least once a week is often a cause of barrenness among cows and heifers. A bull should never be allowed to run with the herd; that is one great point often neglected, and results not only in inducing barrenness, but also in producing abortion among the females. It is one of the most common, yet most pernicious practices indulged in by breeders, more from carelessness, and a desire to save trouble, than want of knowledge.

Steaming Roots for Stock.

A subscriber from Yarmouth, Nova Scotia, asks us to give, through the columns of the CANADA FARMER, the least expensive mode of steaming roots for hogs, on a small scale.

Among other experiences of farm husbandry, one of our regular contributors has carefully tried and practised the following plan both in England and Canada, and having at command small means, the annual expenditure was kept very low. His account is as follows:

For a small inexpensive rig for steaming roots for stock, I have used and would recommend an ordinary potash kettle, if the farmer has one, (of course a better boiler would do its work quicker,) set in a brick arch, with plenty of fire room, and about ten feet of ascending chimney, and a cover fitted into the kettle, made of two-inch dry plank, well jointed, and nailed firmly on scantling to prevent warping. A bar of wood passes across the cover and another crosses this, and each end is firmly secured to the "lug" or propelling support of the kettle, (there are usually four of these "lugs,") by a piece of iron hoop formed into a band, and well hooped on to each projecting end. These bars will firmly hold the cover in its proper place. All round the edge of the cover you must caulk cotton-batting or flax, driven well into the joint, so as to be steam-tight. This is very easily done, as there will be no pressure. A barrel with one head out is placed on the cross, and communicates, by means of a cock, with the kettle below. The barrel is to be filled with water; and the boiler below, as the water evaporates, is supplied from this source.

A two-inch wrought iron or tin pipe, well wrapped over with old rags to keep in the heat, rises, by means of an elbow, from the cover, and turns at once over the side of the kettle, and with another elbow fits into a short piece of pipe, called a nozzle, that enters the centre of the back of the puncheon in which the roots are to be steamed, close to the bottom, and underneath a perforated false bottom placed in the bottom of the puncheon, on which the roots rest. This is supported by two-inch bearers arranged across the puncheon head to receive the weight of roots, and must also allow of the steam freely passing all over the under side of the perforated false bottom. To get rid of the condensed water, without letting the steam escape also, requires a small piece of lead pipe, bent like the letter *v*. The upper end enters the puncheon, below the false bottom, and the lower end is left sufficiently long to be below the double, thus forming a syphon; half-inch lead pipe will answer well. The water, as it condenses, will flow out of the lower end, without allowing any steam to escape. The puncheon is supported by an inch bar of iron passing through the lower part about fifteen inches from the bottom, and must be about six inches longer each side than the width of the puncheon. Two posts are driven into the earth, one on each side, with notches cut in the top to allow the projecting ends of the iron bar to rest in.

A square hole is cut in the upper head of the puncheon, to admit of the roots being filled in with a shovel, and emptied out. The piece that comes out forms a good cover to go back again, if a piece of blanket or cotton cloth is placed over the hole before the cover is put in, and this serves to keep in the steam and is sufficiently tight.

The puncheon is now in its place, the pipe connected with the nozzle, and a piece of cotton wound round it to keep it steam-tight. The syphon pipe, or leak water, is inserted on any convenient side. The boiler is filled with water, and the barrel on the top also. The fire is lighted underneath, and the whole arrangement is complete, with the exception of covering the lid of the kettle with about two inches of sand, which will prevent any small escape of steam, and keep in the heat. We now remove the square cover and fill the roots into the puncheon. If potatoes are used, they want no cutting; if mangolds are wanted, or turnips, they must be cut into pieces about the size of a goose egg. The puncheon can most readily be supplied with a hand-barrow, with handles at each end, and the same barrow serves very conveniently to remove the roots when steamed. To do this you must place the barrow in front of the puncheon, disconnect the pipe at the back, and gently upset the puncheon (it will readily turn on the projecting ends) and all the roots will run out into the barrow. I used, for many years, an ordinary wine cask, that held about 120 gallons; and if good steam is used, with good dry wood, about one hour would steam the puncheon full of roots; but, of course, the time required much depends on the draught, mode of setting chimney, and general arrangement.

The foregoing plan is cheap, efficient and simple, and within the reach of any farmer fit to keep a pig. Of course frost must be guarded against, wherever steam works are used, as cocks and pipes will burst if left full of water. The potash kettle, however, will not be injured by frost. In setting the kettle allow plenty of room for fire all around and underneath.

Cattle Stalls and Manure.

To the Editor.

SIR,—Referring to the letter of "Byreman," and your answer in the February number, I perfectly agree with you in your method of stabling and fattening stock, but you do not finish the story, and say what is to become of the manure after being taken from the byre at such short intervals. Is it to be thrown out to be wasted by the rains, or put under covered sheds to accumulate till wanted in the spring, or carted at once and spread on the frost on the fields where wanted, or piled in conical heaps in the fields?

Allow me to point out what appear to be the objections to these different methods, with a view to promote discussion, and also to gain information on this most important subject. It is unnecessary to speak of the first plan, as every intelligent farmer knows that it is ruinous. If put under sheds till spring, it is only farmers dunging small portions of land that can possibly delay their work till so late. If to be carted at once to the fields, it would be necessary that a farmer, by the plan you recommend, should have sufficient stock to keep a cart constantly employed, and even then, continuance of bad weather would cause great inconvenience. As to whether it should be made in heaps in the fields, or spread directly on the ground, I think, judging from the contradictory opinions of eminent chemists, and first-class agricultural journals, it is hard for the ordinary farmer to decide what to do.

I should propose a modification of your plan; the space behind the cattle should be so arranged as regards depth and width, that sufficient manure should be allowed to accumulate to make it a day or half a day's work for the teams to cart it to the fields to be dunged. I cannot see any objection to this, but I have never tried it.

I cannot agree with you in your objection to box feeding, having tried it for a number of years. Although living on a cold, exposed hill, we often have to leave the doors open to prevent the cattle from sweating, but I do not altogether believe in box feeding, as you cannot economise space sufficiently, and I believe that straw should be all turned into food, instead of bedding. I consider that the simple question of floors for stables in your February number involves one of the most scientific questions the farmer has to deal with in the present day; for if we can make and cart our manure to the place we want it all winter, it does away with one of the greatest drawbacks to Canadian farming. I hope that this subject will be taken up and discussed by abler hands. A FARMER.

Windsor, N. S.

SALE OF STOCK.—Mr. Ashworth, of Belmont, Ottawa, has sold his shorthorn bull, The Viceroy of Belmont, got by Sweetmeat (20924) out of Souvenir of Thorndale by 2nd Grand Duke (12961), to the Hon. B. Seymour, of Port Hope.

Veterinary Department.

Symptoms of Navicular Disease.

The professional veterinarian generally has little difficulty in detecting a confirmed case of navicular disease, but it is often puzzling to the casual observer or amateur, and mistakes in consequence are often made. The horse is always more or less lame, and the lameness is greatest when the animal is first brought out of his stable in the morning, at which time he generally walks with a tripping action, gradually becoming freer in his movements after exercise, and when warmed up to his work he appears to go almost sound. When standing he favours or points the affected foot, and when both feet are alike diseased, he keeps pointing with one foot, then pulls it backwards and favours the other. In severe cases, he seldom stands firm upon both fore feet at one time. The heels become contracted, and general atrophy or wasting of the foot is also the result. This is easily noticed when the disease is confined to one foot, for it becomes considerably smaller than its fellow. The toe of the shoe is also worn quickly down from the peculiar action. The muscles of the limb also waste, and more particularly the muscles on the outer part of the shoulder; and this wasting is often taken for the cause of the lameness, when it is only the effect. It is this condition of those muscles that often misleads as to the true nature of the disease, and the horse is supposed to be lame in the shoulder, when he is in reality a confirmed cripple from navicular disease. These symptoms may continue the same for a considerable time where the horse is moderately worked, but if he is hard wrought, they become more aggravated, until the horse is completely useless for any ordinary work, and particularly so when he has to carry weight. If the foot is taken up, and the sole at either side of the frog struck gently with a hammer, he at once evinces pain, shown by pulling his leg quickly and forcibly upwards. Pressure with the the thumb upon the tendon immediately behind the frog will cause him to act in a similar manner. The above are the general symptoms of navicular disease. Exceptional cases are met with, where the foot is not contracted, and also where the horse points but very little.

The treatment of confirmed cases of this disease can only be of a palliative nature. In recent cases, however, a complete cure may be effected. The horse

should have rest, the shoe be removed, the sole moderately thinned down, and the toe shortened; then poultice the foot, or stand the horse in moistened clay, or a water bath. This treatment should be continued for several hours daily, and the horse afterwards be put into a stall or roomy horse box. After a time, blisters around the coronet are also beneficial, and even frog setons; and in horses that are incurably lame, the operation of neurotomy may be performed, but should only be attempted by a person conversant with the structure of the foot and limb, and only resorted to in inveterate and incurable cases.

Symptoms of Acute Laminitis.

This severe disease is indicated by the excruciating pain exhibited by the suffering patient. The animal is almost unable to move, and when forced to walk, he progresses in a very peculiar manner, by placing his hind legs well forward under the body, in order to relieve the fore feet. The breathing is increased greatly in some cases to such an extent that on a casual glance the animal might be supposed to be affected with an acute attack of pleurisy. The circulation is very much quickened, the pulse beating sixty to eighty per minute, the temperature of the feet is raised, and the pastern arteries are throbbing. The muscles of the shoulder and flank are quivering, and in some instances the horse perspires freely. The bowels are usually costive. If you take the horse by the head, and attempt to force him backwards, he draws the fore feet along the ground. If you attempt to turn him around, the effort to do so will almost cause him to fall. When standing, he keeps his fore legs well out, throwing the weight upon the heels, and the hind legs are brought far under the body, giving to the loins a somewhat arched appearance. This symptom frequently misleads as to the seat of the disease, and the horse is supposed to be affected in the region of the kidneys, when he may be suffering from an acute attack of laminitis or founder.

Inversion of the Womb.

Mr. Richard Serson, of Fulgrove, enquires what is the proper treatment to be adopted when cows "put out the calf bed," and mentions also that he has noticed "cows, and especially heifers, in high condition, swell very much about the navel for a considerable time before they calve."

Inversion of the womb frequently follows the convulsive efforts in the expulsion of the fœtus. The treatment in such cases is to return it as quickly as possible. It should be washed with a little tepid water, and in cases where the placenta or afterbirth is not detached, this should be carefully removed; then support the womb by means of a strong towel, and endeavour to return it by gentle pressure. When the womb is swollen, it might be advisable to scarify it lightly and freely before attempting to return it, but this should be done with caution, and had better be entrusted to a competent veterinary surgeon. Having succeeded in returning the womb into its proper situation, the next object is to retain it there. This is best done by elevating the hind quarters, and applying a pad to the vulva for some little time, which may be secured to a surcingle placed around the abdomen, and behind the shoulder.

Swellings under the belly are often the signs of a good milker, and rarely do much harm. By giving a less quantity of food, and a few doses of the iodide of potassium, their removal will be facilitated.

The writer of the above communication complains that he has written before without receiving any reply. We can only assure him that his previous communications have not reached us. We would, moreover, particularly request our correspondents in general to send communications to the editor distinct, and on different paper from letters enclosing money or treating merely of matters of business.

Hydatids in Sheep's Brains.

To the Editor.

Sir,—I have recently lost two good ewes within a week of lambing. In each of them were found two fine lambs. The sheep both died on the fourth day after the first indications of disease, and the symptoms being peculiar and precisely similar in both cases, my foreman very carefully examined the last one, to find out, if possible, the cause of death.

I send for your inspection a large grub, which was found close to the brain, and which, I have no doubt, caused death.

The symptoms were, first, a nodding movement of the head, and grinding of the teeth, as if in great pain, then a trembling of the fore legs, and finally, loss of strength in the hind legs, the sheep falling on its haunches, and being quite unable to stand.

They continued to eat, as usual, the first, second, and third day, but took nothing the fourth day, when they died. S. G.

Reply—The grub shown us appears to be of the kind frequently met with in the brain of sheep that are affected with the disease known as "sturdy," or "gid." It is called the *Cœnurus cerebralis*, and it is believed to be produced from the ova or larvæ of the tape worms which are dropped from dogs. The minute ova or larvæ may be taken into the month from off the pasture or other food, and so taken into the stomach. They are exceedingly minute, enter the circulation with the chyle, and thus gain access to the brain by means of the blood. The soft, loose texture of the brain is favourable to their further development. In the brain they usually become enclosed in a membranous sac From their situation, they give rise to various symptoms, often such as stated above, whilst in other cases the head symptoms are more alarming and severe—the animal reels about, wanders from the rest of the flock, and in some instances keeps continually turning round and round, plainly showing that the brain is the seat of disease. The hydatid frequently causes partial absorption of part of the skull bone, immediately over its situation.

The remedy in such cases is to remove the hydatid, which is often successfully accomplished by the use of a small trochar and canula. In operating, the head must be carefully examined, to find the seat of the hydatid, which is frequently indicated by a softening of the bone, as already stated. The skin is dissected back, and the trochar and canula introduced; and it is also necessary in some cases to use a small syringe to draw out the hydatid. The after treatment consists in bringing the edges of the wound together, and using any simple dressing. In many parts of Britain the shepherds perform this operation in a very dexterous manner, but we would scarcely recommend it in totally inexperienced hands.

There is a disease known as "grub in the head," of which the seat is not the brain, but the nostril, or nasal sinuses, and which is caused by the larvæ of the gadfly. The irritation consequent on the presence of this parasite is very great, but is not usually attended with cerebral symptoms, nor is the complaint commonly fatal.

Singular Local Disease.

To the Editor.

Sir,—There are a couple of farms in my neighbourhood on which every horse that is employed on them any length of time dies through the effects of a disease, stated by veterinary surgeons and others to be the "yellow water." Now, since there is a great diversity of opinion respecting the cause of the disease on these farms, many asserting that it is owing to the nature of the water, I wish you would give your opinion through the columns of your valuable journal respecting the causes of it, and state if it is infectious What means would you recommend to pursue as a preventive, and how would you treat the disease on the appearance of the first symptoms of attack? A SUBSCRIBER.

Nottawa, March 9th, 1870.

Reply.—The disease is produced, in all probability, from some obnoxious herb, or possibly impure water. We cannot think that the disease is infectious. "Yellow water" is such a vague term that it is impossible for us to form an opinion as to the nature of the malady. Perhaps fallowing, or green-cropping the land, and also dressing with lime, might improve the quality of the grasses, etc.

The Dairy.

Standard Butter and Cheese.

To the Editor.

Sir,—I send you the following extract from an English newspaper, and it would be well for our farmers to bear in mind that similar cases are not rare.

"Fancy Bread and Nasty Butter.—At the Sheffield Town Hall recently, a provision dealer named Charles Fielding, was summoned under a borough by-law, for being in possession of about 350 pounds of butter, which was in a nearly putrid state, the smell being worse than that of manure. The defendant, who does a very large business, did not deny that the butter was bad, but said that he generally sold it to confectioners, who made fancy bread, etc., with it. He denied that he retailed it in the shop, and said that he had for seventeen years sold it to confectioners at about nine pence psr pound. *It was Canadian butter*, and he had sometimes about 200 firkins (nearly 17,000 pounds) of it on his premises. The Bench commented on the case, and ultimately ordered the butter to be destroyed, and inflicted a fine of twenty shillings, the extreme penalty under the by-law."

It is incredible that all the bad butter this dealer sold was Canadian; in fact he could not have obtained it for seventeen years; yet such a statement leads many to infer that Canada really sends an immense quantity of this sort of stuff to the British market.

What are the facts? Of late years a large quantity of butter has been exported, and this has been of quite a mixed quality and value. Some has been good butter put in bad packages, which have either spoiled its keeping, or imparted bad flavours; some has been bad at first, and although put in proper wood, its value could not be increased. Some has been injured by too large a proportion of salt. But the larger part of the bad butter has never been thoroughly or properly worked; such may be said never to arrive at its destination in a wholesome condition.

It is certain a large quantity of this kind of produce is passed off as coming from wrong localities, and Canada is often made the scape-goat for bad butter, cheese, etc., that never even crossed the Atlantic. Let our farmers unite, in different localities, and what they have to spare of these articles make well, handle and pack carfully, and mark with distinctive brands—raise the standard, and in a short time their produce would be in request at greatly advanced rates. R.

A case of hydrophobia in a cow is reported in the *Farmer* (Scottish) of February 2nd. During the past few months, it is stated, many cases of the kind have occurred in the same neighbourhood (Alcomden, near Hebden Bridge) among pigs, cows, and horses, as well as among dogs and cats, and several instances of the disease in the human subject are also reported.

Feeding Dairy Cows.

At some of the Dairymen's Conventions that have been recently held in various places this matter has been discussed by different parties, and all seem to be impressed with the idea, as brought out by the relation of several actual experiences, that in order to obtain the largest amount of actual profit from cows kept for the sake of their product, in the form of butter and cheese, it is necessary to give them some extra feeding in the summer beyond what they obtain from the pastures. One told of expending $25 per head on his cows from March to November, over and above the value of their pasturage. During April and May he gave each cow a mixture composed of four quarts of corn and oatmeal, one quart oil meal, and eight quarts bran per day, in addition to hay. After they went to grass the meal and hay was left off, and twelve quarts of bran per day given. As soon as sowed corn was fit to cut for fodder, and the pastures began to dry up, he gave them cut fodder in addition. His cows gave an extra yield under this treatment of 200 pounds of cheese each over cows on pasture alone, and were besides quite fat at the end of the season, and so worth at least $10 per head over what they would have brought if in ordinary condition. So that for an investment of $25 each he realized $35 each, or $10 profit per head over what he would have had on pasture alone. Besides this, the extra feeding enabled him to keep forty cows on pasturage that without it could have kept but thirty-two, and this added to the profit made on the feed, gave him an extra profit of $755 over and above what he would have had without using the extra feeding. This matter of extra feeding of cows when at grass ought to obtain place with our best dairymen, and the actual results of even soiling the cows with corn fodder while at grass, would, no doubt, show largely in favour of the practice.

It was resolved at a meeting in Derby, England, February 18, convened by the Derbyshire Agricultural Society, to establish three cheese factories in the county on the American principle.

At a meeting of the Little Falls Farmers' Club, Mr. Willard said his observation led him to believe that it was better to have one large pasture than to alternate from one to another. The feed was more uniform and the result more satisfactory. It was thought that it would take in Herkimer county from one and a half to two acres of pasturage to keep one cow. In some very fine pasturage, an acre would suffice.

The cheese factory at the front of Sidney was built in 1866, and cost, including all apparatus, double sets of cans for each shareholder, and six spring wagons, the sum of $6,318. In 1866 the cows numbered 250, which increased in 1869 to 750. In 1866 the grass receipts were $9,980,04, and in 1869 they amounted to $23,422 34. The total amount of all the expenses is about two cents per pound of cheese. All the trouble the stockholders have in connection with the matter is to deliver the milk at the cow stables, and draw a check for their money at the close of the season.

Poultry Yard.

Golden Pheasants.

It is a commonly prevailing opinion that the Golden Pheasant is not a hardy bird—a mistaken idea. When I resided in Woodstock, Ct., I tested that thoroughly. All that is needed for their protection in winter is to have some clumps of evergreens in the lawn, say eight or ten feet in diameter. Under such cover my pheasants have remained all winter, being in perfect health. Towards morning, you will hear the Golden Pheasant cock begin to crow lustily, with a sharp loud crow, as much as to say, "We are all well." The latter end of April or beginning of May the female bird begins to lay. She will select her nest in some easy place, and lay from 14 to 19 eggs. She ought not to be disturbed or frightened off her nest; if so, she will drop her eggs anywhere about the enclosure. When she began to sit, I used to take the eggs and put them under a small bantam. They are twenty-four days coming off. When hatched out, take them with the bantam mother and put them in a square box; four boards nailed together, about four feet long and twelve inches high, will answer; let them fit close to the ground. Give them no food for twenty-four hours, then give them hard boiled egg, with lettuce chopped fine, varying the food: sometimes a little curd, breadcrumbs wet with a little sweet milk. The more varied their food and the more frequently renewed, the better. At two or three months old, feed them on barley, oat grits, etc

I have often thought—think so now—that a gentleman's lawn is not complete without these harmless pets. A neat wire fence, five feet high, is all that is required to keep them. Then they can have these beautiful birds in all their gorgeous colours.—*Cor. in Western Rural.*

Turkey Raising.

With many farmers, the raising of turkeys is a precarious business, owing to the tenderness of the young during the first month, or two months after they are hatched. Success in the management will depend much on the situation of a farm. A warm southern exposure for the farm buildings, and ample grounds for the young to exercise, without strolling too much in the wet grass, and warm places to retreat into in cold and wet stormy weather, are the chief requisites to succeed in raising a flock of turkeys. They will subsist on any of the different kinds of grain raised on the farm; it is only the manner of feeding which is important. They require to be fed little and often, and if the women folks will take an interest, there will seldom be a failure. Vermin should be carefully guarded against; by coming in contact with other poultry and having access to their houses, the young turkeys may become infested with

lice, which will be a great drawback to their growth, and perhaps cause a failure to raise a brood. For five years past I have discontinued keeping turkeys, finding them not very profitable when there were no conveniences to restrain them from committing depredations on the crops. But since I have no turkeys on the farm it has been sadly overrun with grasshoppers, and for two years past they have totally destroyed my turnip and ruta baga crops. I will try raising turkeys again, to see if it will rid me of the grasshoppers. Fifty turkeys roaming in the fields, in a week's time will destroy bushels of these pestiferous insects. If wild turkeys can be obtained and domesticated to cross with the common stock, it would improve the size and make them more robust to bear the rain and wet grass, and therefore more easily raised. By crossing the breed with wild turkeys, the progeny will be more of hunters of flies, bugs and other insects, and less inclined after grain, and of course more profitable. I saw in Mifflin County a domesticated wild turkey gobbler, a beautiful fowl, his colour brown and snuff, with plumage having a lustre and brilliancy almost equal to the peacock. The wild turkey gobblers do not come to maturity till they are about two years old; the one in question was a large noble bird, twelve months old, but had not commenced to gobble. Fifty of such gobblers as I raised years ago, to take to market the coming Christmas, would bring a handsome pile. I have had on my premises turkeys weighing as much as forty pounds. But turkey raising is attended with much trouble and care, and if not properly managed will be a losing concern, and were it not that I am so sadly harassed with grasshoppers, *nary* turkey should gobble on my farm.—*Cor. Journal of the Farm.*

Poultry Association.

To the Editor.

Sir,—At the meeting of the Board of Agriculture, on the 24th February, Professor Buckland proposed a grant to the Ontario Poultry Association.

Mr. Rykert opposed the motion on the ground that a good deal of complaint had been made respecting the exclusive character of the Association.

I should be obliged if he would also state by whom the complaint was made. As one of the original promoters of the Society in 1866, I shall be fully borne out by its members in saying that in the first instance we called it the Canada West Poultry Association, and when the Province, on the formation of the Dominion, became Ontario, the word Ontario was substituted for "Canada West." This was done, in both cases, to obviate any such idea as that now started by Mr. Rykert.

The membership is open to all. The competition is not restricted to any part of the world; but why the citizens of Toronto, who have *solely* contributed in a most liberal manner to the prize list and expenses of the four exhibitions that have been held, should do so for the amusement of other cities, it is difficult to understand.

I am safe in saying, I believe, that not one cent, exclusive of membership and entrance fees, has been gratuitously contributed towards the benefit of the Society outside of Toronto, except in one instance, when a distinguished exhibitor from Montreal returned his prize money as a donation to the Society. A circular was sent to individual members at the commencement of this year, asking for voluntary contributions towards the expense of a fifth exhibition. What was the result? Several prominent members from a distance requested their names to be erased from the Society's books; and to judge from the response received outside of Toronto, it would appear that if, as Mr. Rykert appears to wish, exhibitions are to be held at St. Catharines, Hamilton, and other cities, the $100 proposed as a grant will have to be multiplied by six to enable the plan to be carried out.

Towards the expenses of a show in April next some few—three or four—not in Toronto, have proposed to give; but I believe this is the first instance of the kind on record. If Mr. Rykert will examine the list of awards at the four exhibitions I think it will be seen that most of the exhibitors were not from Toronto, and that most prizes were sent elsewhere.

The constitution and records, and the uniform practice of the Association, will clearly prove to any unprejudiced person that there is really not the slightest ground for this most unfair charge of exclusiveness. It is the country that we aim to benefit, and to the country at large, without favour, the membership is open; and the fact of the exhibitions being hitherto confined to one place has been a matter purely of economy—indeed, of absolute necessity, on the ground of expense.

F. C. HASSARD.

The Nova Scotia Dog, Pigeon, and Poultry Club propose to hold a show in Halifax in June next, provided the requisite funds can be obtained. T. D. Almon, M. D., is the Secretary.

Change of Colour.—Mr. Andrew Russell, of Packenham, who has kept Black Spanish fowls for some years, was surprised to observe lately the plumage of one of his full-bred Spanish hens changing colour; she is now pure white.

Influence of Railroads on the Hatching of Eggs.—A peculiar effect of the proximity of railroads on the hatching of eggs has been mentioned in various papers. It has been found that there are scarcely any chickens raised in poultry yards which are situated in the immediate neighbourhood of the rails of a much frequented railroad. This fact is supposed to result from the earthquake-like trembling shaking the soil caused by passing trains, which exert an unfavourable influence on the eggs.—*Ex.*

Entomology.

Imported Insects and Native American Insects.

If we examine into the history of the imported Currant Worm and the native Currant Worm, we shall find a very curious state of things. These two insects both produce sawflies, which are so closely allied to each other, that although they are referred to distinct genera by entomologists, it may be doubted whether the genus (*Pristiphora*) under which the native species is classified be not a mere subgenus of that under which the imported species is classified. Reasoning *a priori*, therefore, we should expect to find a very great similarity in the destructive powers of these two worms, especially as each of them infests the leaves both of the red currant and of the gooseberry. But what are the actual facts? On the one hand we see a Native American species, which must have existed here from time immemorial, feeding on our wild gooseberries and perhaps on our wild red currant, and which yet has troubled our cultivated gooseberries and red currants so very slightly, that it cannot be proved with absolute certainty to have ever done so at all, except in Rock Island County, Illinois, and in Scott County, Iowa.

On the other hand we see a species, only introduced into this country from Europe some twelve years ago, which has already almost put a stop to the cultivation of the gooseberry and red currant throughout a large part of the State of New York, the northern borders of Pennsylvania, and the whole of Canada West, and is slowly but surely extending itself in all directions from the point where it was originally imported. What can be the reason of such a wide difference in the noxious powers of two such closely allied insects, feeding on exactly the same plants, but one of them indigenous to America and the other imported into America from Europe? Nor is this the only case of the kind. We can point out at least three other such cases. The imported Onion-fly (*Anthomyia ceparum*), is a terrible pest to the onion grower in the east, though it has not made its way out west. On the other hand, the native American Onion-fly (*Ortalis arcuata*, Walker), which is a closely allied species, and has almost exactly the same habits, has only been heard of in one or two circumscribed localities in the West, and even there does but comparatively little damage. Again, the imported Oyster-shell Bark-louse (*Aspidiotus conchiformis*) is a far worse foe to the apple and certain other fruit trees than our indigenous Harris's Bark-louse (*Asp. Harrisii*), though each of them infests the same species. Finally, the imported Meal-worm Beetle (*Tenebrio molitor*) swarms throughout the whole United States, and is a great pest, while the native American species

(*Tenebrio obscurus*), which has almost exactly the same habits, belongs to the same genus and is of very nearly the same size, shape and colour, is comparatively quite rare among us, and is scarcely known to our millers and flour-dealers.

On a careful and close examination, it will be found that almost all our worst insect foes have been imported among us from the other side of the Atlantic. The Hessian Fly was imported almost ninety years ago, the Wheat Midge about half as long ago; the Bee Moth at the beginning of the present century; the Codling Moth, the Cabbage Tinea, the Borer of the red currant, the Oyster-shell Bark-louse, the Grain Plant-louse, the Cabbage Plant-louse, the Currant Plant-louse, the Apple-tree Plant-louse, the Pear-tree Flea-louse, the Cheese Maggot, the common Meal-worm, the Grain Weevil, the House Fly, the Leaf-beetle of the Elm, the Cockroach, the Croton Bug, and the different Carpet, Clothes and Fur Moths, at periods which cannot be definitely fixed. Even within the last few years the Asparagus beetle has become naturalized in New York and New Jersey, whence it will, no doubt, spread gradually westward through the whole United States, while the Rape Butterfly was introduced about a dozen years ago, and is rapidly spreading over some of the Eastern States. And only a year ago the larva of a certain Owlet Moth (*Hypogymna dispar*), which is a great pest in Europe both to fruit trees and forest trees, was accidentally introduced by a Massachusetts entomologist into New England, where it is spreading with great rapidity. It is just the same thing with plants as with insects. We have looked carefully through Gray's *Manual of Botany*, and we find that—excluding from consideration all cryptograms, and all doubtful cases, and all cases where the same plant is supposed to be indigenous on both sides of the Atlantic—no less than TWO HUNDRED AND THIRTY-THREE distinct species of plants have been imported among us from the Old World, all of which have now run wild here, and many of which are the worst and most pernicious weeds that we have to contend against. In the *U. S. Agricultural Report* for 1865, pp. 510-519, will be found a list of 99 of the principal "Weeds of American Agriculture," by the late Dr. Wm. Darlington. Of this whole number no less than 43, or nearly one half, are species that have been introduced among us from the Old World. Among these we may enumerate here, as the best known and the most pernicious, Buttercups (two species), Shepherd's Purse, Saint John's Wort, Cow-cockle, Mayweed or Dog-fennel, Ox-eye Daisy, common Thistle, Canada Thistle, Burdock, Plaintain, Mullein, Toad Flax, Bindweed, Jamestown (Jimson) weed, Lamb's Quarter, Smartweed, Field Garlic, Foxtail Grass and the notorious Cheat or Chess. And to these we may add the common Purslane, which through some strange oversight has been omitted in Dr. Darlington's catalogue.

It will be supposed, perhaps, since there are about as many voyages made from America to Europe as from Europe to America, that we have fully reciprocated to our transatlantic brethren the favours which they have conferred upon us in the way of noxious insects and noxious weeds. It is no such thing. There are but very few American insects that have become naturalized in Europe, and even these do not appear for the most part to do any serious damage there For example, on one or two occasions, single specimens of our Army Worm Moth (*Leucania unipuncta*) have been captured in England, but the insect has never spread and become ruinously common there, as it continually in particular seasons does in America. Our destructive Pea Bug (*Bruchus pisi*) has also found its way to Europe, but although it is met with in England, and according to Curtis has become naturalized in the warmer departments of France, Kirby and Spence expressly state that it does not occur in England "to any very injurious extent," and Kirby seems to doubt the fact of its being naturalized in England at all Again, the only species of white ant that exists within the limits of the United States (*Termes frontalis*) has been known for a long time to be a guest at the Plant-houses of Schonbrunn in Germany, but it is not recorded to have ever as yet spread into the surrounding country. As to our American Meal-worm (*Tenebrio obscurus*), Curtis states that it has been introduced into England along with American flour, and that it is sometimes abundant in London and the provinces; but Kirby and Spence say not one word about it, and it seems to be confined to the English seaports and the places where American flour is stored, without spreading into the adjacent districts.

A very minute yellow ant, however (*Myrmica molesta*), which is often very troublesome with us in houses, has, according to Frederick Smith, "become generally distributed and naturalized" in houses in England; and Kirby and Spence state more specifically that "it has become a great pest in many houses in Brighton, London and Liverpool, in some cases to so great an extent as to cause the occupants to leave them." As to our Chinch Bug, our Curculio, our Plum Gouger, our two principal Apple Tree Borers, our Canker Worm, our Apple-tree Tent Caterpillar, our Fall Web Worm, our Peach-tree Borer, and our other indigenous pests among the great army of Bad Bugs, nobody ever yet found a single one of them alive and kicking on the other side of the Atlantic. And with regard to plants, the only two American plants that we know to have become so firmly established in Europe as to be a nuisance there, are an American aquatic plant, the common Water Weed (*Anacharsis canadensis*), which has choked up many of the canals in England; and our common Horse Weed, (*Erigeon Canadens*) which has spread from America nearly over the whole world.—*American Entomologist.*

The Pea Weevil.

To the Editor.

Sir,—Mr. Wm. Langdon, of Brighton township, handed me the enclosed peas, with the request that I would send them to you, as each pea contains what has been thought a curiosity by all to whom they have been shown.

As we are readers of your journal, if you will give in it a description of the insect that is enclosed in each pea, telling its name, when and how it got into the pea, as the insect is perfectly developed in the pea, and yet the skin of the pea is not broken, you will oblige. Is the specimen sent the pea bug, that makes the raising of peas in the State of New York, and some other places, almost a total failure? By giving the information sought in your journal you will answer at once a great many enquiries and oblige many of your readers in this section.

Castleton. DARIUS CROULER,

a, perfect beetle; *b*, larva—both greatly magnified; the accompanying outlines representing the natural size; *c*, infested pea.

Note by Ed.—The peas sent us by our correspondent contain specimens of the Pea Weevil (*Bruchus pisi*). On each pea may be observed a slightly discoloured round spot, which is found on inspection to be caused by a hole in the pea, under the thin hull, containing a small blackish beetle. It certainly at first sight appears strange how the perfectly developed beetle can have got into the pea when the skin is entirely unbroken, but a little insight into the history of the creature explains the seeming mystery. When the peas are in blossom, the parent beetle lays its eggs in the tender pod. From these hatch out tiny little worms, which perforate and enter into the soft newly-developed peas, making a very minute hole, which speedily closes up with the growth of the pea. The worm grows as the pea increases, eating away at the mealy part of it, and usually sparing the germ, till at length it assumes the pupa state, and finally, when the pea ripens, completes its transformation into a perfect beetle. Here it remains, with only the thin epidermis between it and the outer air and liberty, all winter, till the warmth of spring bids it eat through the husk and perform its proper avocations.

It is not long since we gave a brief account

of this creature, in acknowledgment of a number of specimens sent us from Quebec. It is needless, therefore, for us to enlarge farther upon its history.

The following remedies may be mentioned:— Keep the infested peas in tight vessels over one season; that is to say, instead of sowing the produce of last year's crop this spring, keep them till next year. The weevils will soon come out with the increasing warmth, and finding no escape, will die in the vessel before the end of the year; and thus the peas will be free from their attack. Another mode is to dip the peas in boiling water just long enough to kill the beetles, but not destroy the germ. *One minute* is sufficient.

Scavenger Beetles.

In our last article upon insects that are beneficial to mankind, or that are at least of so harmless a character that they should be spared from the universal sentence of death too often passed upon the race, we gave an account of the families whose agreeable occupation it is to act as sextons for the smaller animals, or otherwise dispose of carrion. The next tribes of beetles that come within our present range of observation, discharge a somewhat similar office in the domain of nature, and busy themselves in the removal of nuisances from the surface of the earth.

To quote the words of Kirby and Spence (*Introduction*, Letter IX.),—"How disgusting to the eye, how offensive to the smell, would be the whole face of nature, were the vast quantity of excrement daily falling to the earth from the various animals which inhabit it, suffered to remain until gradually dissolved by the rain, or decomposed by the elements! That it does not thus offend us, we are indebted to an inconceivable host of insects which attack it the moment it falls; some immediately begin to devour it, others depositing in it eggs from which are soon hatched larvæ that concur in the same office with tenfold voracity; and thus every particle of dung, at least of the most offensive kinds, speedily swarms with inhabitants which consume all the liquid and noisome particles, leaving nothing but the undigested remains, that soon dry, and are scattered by the winds, while the grass upon which it rested, no longer smothered by an impenetrable mass, springs up with increased vigour." The insects that engage in this work belong to many different tribes, chiefly pertaining to the orders of Beetles and Flies (*Diptera*). A large proportion of the former come in natural sequence almost immediately after the Carrion Beetles already described, and may, therefore, be fitly reviewed here. To give a complete account of all the different families of beetles that belong to the hordes of scavengers, would be a long, and—to the general reader—by no means an interesting proceeding; we shall, therefore, content ourselves with describing the peculiarities in structure and habits of the common sorts.

The first, and most numerous family, that we come to, includes all those species of beetles called in England Rove-beetles, or Cock-tails (*Staphylinidæ*). They are readily distinguished from all the other families by their peculiarly long and narrow bodies, flattened form, and very short wing covers, which only cover one or two segments of the abdomen, instead of almost the whole of it, as is the general rule with beetles. These short wing-covers give the insect somewhat the appearance of wearing a boy's short jacket, instead of a long coat; notwithstanding their brevity, however, they completely conceal and keep out of the way the ample membranous wings, which, when not in use for flight, are beautifully tucked away beneath them. The long uncovered abdomen is capable of being moved in different directions, and is employed by the creature in folding and unfolding its wings. When irritated or alarmed it cocks its tail over its back, and assumes a ludicrously threatening aspect; it also possesses the power, probably for defence, of protruding at will two vesicles from the extremity of the abdomen, which emit a very unpleasant, and sometimes indescribably fetid odour.

The chief food of these insects, both in the larval and perfect states, consists of decaying animal and vegetable matters; in early summer every piece of dung that falls to the earth speedily swarms with them, and in the autumn they are equally numerous in fungi, agarics, etc. Some species are also carnivorous, feeding upon other insects; in England a large species, commonly called the Devil's Coach Horse (*Goerius olens*) devours large numbers of the destructive ear-wig (*Forficula*); "On the least approach of danger," Westwood relates, "this insect, like the rest of the group, immediately puts itself into a most ferocious-looking posture of defence, throwing the tail over the head like a scorpion, protruding the anal vesicles, elevating its head, and widely opening its long and powerful jaws."

Upwards of four hundred species of this family of beetles are found in North America, and of these, one hundred and five species have been taken in Canada. Many more undoubtedly remain to be found and described when collectors pay more attention to the minuter forms of insect life. Eight hundred species have been described as found in England alone. In tropical climates they are very rare; their places as insect-scavengers being supplied by the excessively abundant ants and termites.

Look Out for the Colorado Potato Beetle!

The potato growers in the extreme western part of Canada must not be surprised if they find a new and most destructive insect appearing upon their plants this year. The hosts of the terrible Colorado Potato Beetle (*Doryphora 10-lineata*, Say) are steadily marching on in their journey from the Rocky Mountains to the Atlantic Ocean; they have already made their way into the neighbouring State of Michigan, and either this summer or next we may expect to hear of their invading our shores along the River St. Clair. Should this insect obtain a footing in our country, we can assure our readers in all earnestness that they will find it a far more grievous nuisance than any horde of Fenians with which we have ever yet been threatened, or are likely to be troubled with; the ravages of this small foe would undoubtedly prove a far greater source of pecuniary loss and inconvenience to the whole country than any raid of these barbarous ruffians. To be "forewarned" is, to a great extent, to be "forearmed;" let us then be on the look-out for these creatures, and be prepared to repel their attacks whenever they begin to advance upon our land. Kill every one that comes, and show them no mercy, is our advice to our readers; do not wait till they get a foothold in the country, but destroy them immediately upon their arrival; and let those who live along the St. Clair keep a good look-out for their appearance.

The history of this insect is rather a curious one. For many years it was known to feed upon a wild species of potato, peculiar to the Rocky Mountain region; but when civilization, and the consequent culture of the tuber, advanced so far westward, it soon acquired a taste for the cultivated varieties, until in 1859, by advancing eastward from one potato patch to another, it reached a point one hundred miles west of Omaha, in Nebraska. In 1861 it began to appear in Iowa; in 1864 and '65 it crossed the Mississippi River, and invaded the State of Illinois. At that time the late Mr. Walsh predicted (*Practical Entomologist*, vol. 1) that it would in all probability "travel onwards to the Atlantic, establishing a permanent colony wherever it goes, and pushing eastward at the rate of about fifty miles a year." This prediction has, so far, been fulfilled in a remarkable manner; in 1866 it invaded Southern Illinois; in 1867 it passed into Western Indiana and the south-west corner of Michigan; in 1868 it had reached Ohio, and the south shore of Lake Superior in the north-western corner of Michigan; last year it went over a great portion of that State, and therefore this year we may expect it in Canada.

This insect when seen in a cabinet is a very beautiful creature; its body is cream-colored, its wings of a bright rose color, and its wing-covers are adorned with five deep black stripes. Farmers and gardeners, however, whose potato crops are blasted by it, do not usually discern its beauties, but consign it to speedy and unhesitating destruction. It feeds upon the plants in both its larval and perfect states, driving everything before it. Should any of our readers have the ill-fortune to find it in their fields this year, we beg that they will send us some specimens, in order that we may give a further and illustrated description of them.

Potato Beetle.

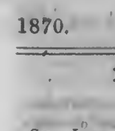
To the Editor.

Sir,—In an article on the Colorado Potato Beetle you give an interesting history of that destructive insect, and caution gardeners and farmers, (and I am a little of both) to be on the lookout this year for this new pest, an enemy to the potatoes. I live four miles to the east of Guelph, close to the Grand Trunk Railway, and, if I mistake not, the beetle you describe at the end of your article was here last July in hundreds on my potatoes; on a hot day somewhere about that time, I was hoeing my Early Goodrich Potatoes, and saw a few strangers, to me, of the beetle tribe on the leaves of the potatoes which were very rank; and just at the time they were coming into bloom I was at work amongst them again, and that was on a hot day too, (I try to kill weeds on such days), these gay beetles were pretty numerous, both on the potatoes and flying about, and I was particularly struck, both by their *beauty* and their *numbers*, and thought at the time that they meant no good.

I have nothing to guide me, but the enclosed sketch is, according to the best of my recollection, something about his size, and it struck me when they were on the green leaf, that they were black and white, and when on the wing, pink looking; and, unlike some other beetles, they are easily killed by the finger and thumb, for I did kill a good many in pairs, male and female; but I did not observe that they injured my crop, and I saw none afterwards. L.

Eramosa, Ont.

Note by Ed.—The specimens observed by our correspondent on his potatoes, judging from his description and sketch, belonged to the species called the "Three-lined Potato-beetle" (*Lema trilineata*, Oliv.). The annexed wood-cut represents the insect a good deal magnified. This is a very common species in Canada, and occasionally becomes rather destructive. The Colorado Beetle is much broader and rounder in form, as well as a good deal larger, and may be recognized by its *ten* dark stripes on the wing-covers, five on each; whereas, our insect has only *three* black stripes; one down the middle, and one on each side. The Colorado Beetle could hardly have travelled as far east as Guelph without having been observed by some of our entomologists.



Live Beetles.

"A young beginner," residing in the township of Waterloo, has sent us some lively specimens of beetles that we should hardly have expected him to meet with at this time of year. The sight of them immensely delighted our entomological eyes, that have gazed upon few living specimens of insects for some months past, the more especially as everything about us is just now covered with a couple of feet of snow, and the prospect of a "beetle hunt" is obscured by the haze of the apparently far distant future.

The specimens belong to three distinct species. (1). A long, slender Capricorn beetle (*Toxotus decoloratus*, Harris), about an inch in length, and with antennæ but little shorter than the body, of a pale drab colour, with shining reddish head, thorax, legs, and antennæ. This rare beetle our correspondent found in a "damaged birch tree," the wood of which, no doubt, served its larva for food. It belongs to a family whose numerous members are all wood-borers, but we believe that no one has hitherto discovered what particular tree this species attacks.

(2). A shining, deep chestnut-brown beetle, about half an inch long, belonging to the same family, and much resembling the only too common Meal-worm (*Tenebrio molitor*, Linn.). It is a species of *Uloma*, the members of which feed upon decayed wood, and also upon wheat, flour, etc. The specimen sent us, our correspondent found "in a decayed beech tree."

(3). Two specimens, male and female, of a small species of Stag-beetle (*Ceruchus piceus*, Weber). These insects are about half an inch in length, of a pitchy-black colour; the male is remarkable for his highly developed jaws, which are longer than his head, and furnished with two large teeth apiece, giving him a very formidable appearance. Some species of this family are of very large size, and furnished, in the males, with enormous toothed jaws, somewhat resembling the branched antlers of a stag, whence their common English name. Most of the species, including the one before us, feed upon the juices of decaying wood, and cannot be considered injurious. The large Stag-beetle of Europe (*Lucanus*) causes, however, much damage to the Willow and Oak, boring into the solid wood and also into the roots of the tree.

We must commend our correspondent's careful packing of these specimens; the little box, scooped out of a block of wood, in which they were enclosed, would defy the "stamping" of even the most energetic postmaster. We must also congratulate him upon his success in obtaining such good and rare specimens for a beginning; we hope that he will continue the pursuit, which he will find attended with much unalloyed pleasure.

A Cheap Grubkiller.—Dissolve a coffee-cup full of salt in hot water, then put into a common sized watering pan, and fill up with cold water. Just give each plant a gentle switch over with this mixture, and they will disappear in a moment, and the salt and water will nourish the plants wonderfully. All greens are fond of salt and water. Some people would be afraid of killing their cauliflowers; but it must be borne in mind that the salt and water will not penetrate the leaves. It runs off to the roots, killing every caterpillar in its way.—*Gardener's Magazine.*

Correspondence.

Which Kind of Barley Shall We Sow?

To the Editor.

Sir,—It appears to be of rather unusual importance, just now, to arrive at correct conclusions in reference to the above question. I believe that in attempting to do so it is necessary to consider the merits of two kinds only of barley—the six-rowed and the two-rowed—the four-rowed being little known in Canada and the States.

The six-rowed is by far more largely cultivated in both countries than the two-rowed, but the two-rowed is the favourite with the malsters and brewers in Great Britain, and is, in the experience of many farmers here, the more profitable crop, and, unquestionably is the finer, plumper, heavier grain. If, therefore, our choice is to be governed by the intrinsic comparative merits of the two varieties, there can be no difficulty in deciding upon the two-rowed. One thing is certain, it is becoming an absolute necessity to decide upon one or other of them for general adoption; for, as in the process of malting there is a difference of several days in the period at which the two varieties sprout, and as the merchants are unwilling or unable to provide separate accomodation for each sort, it follows that the two kinds are huddled together into one general receptacle, and that the malting process becomes one of confusion, embarrassment and loss.

The merchants appear to agree in the opinion that the two-rowed is the superior grain, and that the desirable thing is to get it generally adopted; but they are becoming urgent for the universal adoption of one of them.

The present mercantile view of the question is thus put by the *Albany Journal*:—"Six-rowed has been the favourite with malsters here this season. In this connection we would state that farmers would find it to their benefit, in their selection of seed this spring, to buy six-rowed 'Canada West.' Six-rowed must supersede two-rowed, for even this season it has commanded twenty-five cents more than the two-rowed."

Now, this writer may be correct enough about the present commercial values of the two kinds of barley, but I very much question if he knows anything about the grain beyond its present relations to the market, which may soon be reversed.

Shall we, then, unite with the increasing numbers of those who are anxious to promote the adoption of the beautiful two-rowed barley; or shall we at once yield to the present (perhaps only momentary) mercantile view of the case, and sow six-rowed?

DANIEL D. SLADE.

Oshawa, March 9, 1870.

Barn.—We will attend as soon as possible, though we cannot do so at once, to our correspondent's request, and give a plan shortly.

"Name! Name!"

To the Editor.

Sir,—Will you allow me the use of your columns to give a few homely words of advice to my brother farmers. I would say to them, one and all: Unfurl your bunting; spread your banner; exhibit your sign, and let the rest of the world know where you live.

I am led to take up this matter from seeing in your columns so many fictitious names to really good articles, written by those who have evidently practical experience of the subjects on which they write. Now, the withholding the name deprives the reader of a considerable part of the advantage and worth of the article. For instance, a writer some time ago gave an account of his experience with a variety of potatoes, some of which I had never tried, and I should have been glad to have applied to him for seed had I known his address. The man who writes a good article, and signs no name or a fictitious one, resembles him condemned in Scripture who "puts his candle under a bushel."

By all means let us have these communications from practical men and veritable farmers, but let each writer sign his own name, and give his post office address. I would further advise every one to mark everything that belongs to him—his waggons, sleighs, carts, bags, &c., and above all the rest, his gate or gate posts, as a guide to those who wish to see him. This custom would save many a vexatious, fruitless journey, and would maybe bring the farmer a welcome caller or customer, that would have been lost to him without the precaution. The name on the waggon or carriage would be a capital advertisement, the value of which all men of business know well and do not forget to take advantage of, and those who wished to see the proprietor would hunt him up. Try it, farmers. A. B. BROWNSON.

Bayfield, Ontario.

Note by Ed.—We always like, and indeed require, the names of correspondents, as evidence of good faith; but it is optional with the writer to have it published. No doubt, to the reader there are advantages in giving the name, and the article will often in consequence be perused with greater interest, and have greater weight. But there is one abuse of the practice against which we must take occasion to protest, and that is, making use of our literary columns for gratuitous advertisements. When a person has anything he wishes to bring before the public for sale, let it be agricultural produce, implements, or merchandise of any kind, it is not fair to expect a gratuitous insertion of a letter or article containing the information, and the vendor's name and address, along with the ordinary reading matter of the journal. The place for such communications is the advertising columns, and the price for their insertion the ordinary advertising rates.

Weather, Hay and Grain in Hastings.

To the Editor.

Sir,—We are, at this date, literally snow-bound—a universe of sky and snow. Fences invisible; windows almost hidden; trees covered as high as their branches. Still, we will not complain, this is a blessing in disguise, a mantle thrown over the bosom of mother earth, cherishing her offspring. Underneath this veil are the fair features of youth and promise.

The crop of clover seed in this vicinity is nearly all thrashed and marketed. The yield here is light, the seed inferior compared with other seasons. The wet season promoted the growth of stalk, leaf, and blossom, at the expense of the seed. In clays and calcareous soils the yield was better. It is proving a remunerative crop, though some contend that it, i. e., the seed growing, exhausts the soil. A very wet season favours the advantage to be derived from plaster, owing, no doubt, to the attraction of that absorbent for moisture.

There is an abundance of hay in the country, it is difficult to find market for it. I think it would pay to press and bale it for some foreign market, or to be held over for a year of scarcity, or better, convert it into beef and mutton. There seems to be great need of a change in the varieties of grain grown here. There is not as good a yield of spring wheat as there should be, especially "Fife." While there is a mania for new and extraordinary potatoes and oats, we hear very little of spring wheat.

J. M. LE BOUTILLIER.

Sidney, March 17th, 1870.

Capacity of a Root Cellar.

C. R. wishes to know what space he must provide in building a root cellar for storing turnips, or how much to allow for a bushel of the roots.

It will be sufficiently accurate for this purpose if he calculates one cubic foot and two-thirds (1⅔) for each bushel, or 16⅔ feet (in decimals about 16.66) for every ten bushels. An easy way of reckoning is to use the rule for measuring corn in the ear, which is as follows: Measure the length, width, and depth of the crib in feet; multiply these three dimensions together, and the product by 4; cut off the last right-hand figure; those to the left express the number of bushels of corn if the ears were shelled. Add one-half this amount, and you will have about the quantity of bushels of turnips in the same space. For example, suppose a space of 10 ft. x 20 ft. x 8 ft=1,600 ft. Multiply by 4=6,400. Cut off the right-hand figure, leaving 640—the number of bushels of shelled corn. Add half this. 640 and 320 make 960, which would be about the number of bushels of turnips to allow for the same space.

Plaster of Paris.

A subscriber asks, "what benefit is Plaster of Paris to clay land, or land that overlies a bed of plaster? how used, in raw pulverized state, or burnt? and in what manner is it applied to the land? what effect on light and sandy soils?"

Ans. by Ed.—In the Canada Farmer of Feb. 7th, 1869, will be found an editorial on this subject, from which it will be seen that the chief value of plaster is as a stimulative manure to clover. It is the sulphuric acid contained in plaster that renders it valuable for clover.

It makes little difference as to the soil on which it is applied, provided the object is to benefit the clover crop. Its manurial value on clay lands would not be equal to that of lime, except for clover alone; nor does it, as a general rule, pay to use it as a manure for any other crop than clover, except perhaps when it is applied to the young plants of Indian corn, which is commonly done at the rate of a handful to each hill.

It is always burnt before being ground, and is applied by scattering broadcast over the land, by hand, in much the same way as sowing grain, the usual allowance being from 100 to 200 pounds per acre, according as the clover is thick or otherwise; the thicker and heavier the ground is covered with clover, the more plaster is needed.

Broom Corn.

To the Editor.

Sir,—In a recent issue of your journal, John W. Smook asks if broom corn can be grown successfully in the vicinity of Hamilton. It may be interesting to him and others to learn that I grew it here in Ramsay, of good quality, fifteen years ago, and found that it would ripen in an ordinary summer before the fall frosts could hurt it, so I should conclude that it would do still better in the vicinity of Hamilton, which is some hundreds of miles nearer the equatorial belt.

WM. PATERSON.

Ramsay, Ont.

Clearing Land by Steam.

To the Editor.

Sir,—Some of your readers interested in effective farm machinery will no doubt be gratified to learn that an experiment in drawing stumps by ordinary steam ploughing engines, just tried in England, has met with complete success, and in consequence some hundreds of acres of waste land will be brought into use. These were a few years since covered with Scotch firs, 12 to 20 inches in diameter. Attempts to clear the land of the stumps had failed, from the expenses incurred. An agricultural engineer being applied to, however, contracted to clear and plough the land, set to work two of Fowler's 14 horse power winding engines, and the stumps were easily extracted at the rate of one per minute, two smaller engines being employed to draw away the roots into heaps. A six-furrow plough stood ready to turn over the land as soon as a sufficiently level surface had been made, which would readily be done by the steam cultivator or harrow.

Will not some of our capitalists, or even Government, try the same here? Would it not pay, and pay well? Might not a few acres thus cleared on wild lands render the lots more saleable, and divert hither some of the emigration now tending to the States?

R.

Sugar Beet.—Mr. C. Loyd is referred to the article on this subject in the March number of the Canada Farmer.

Chinese Yams.—Several correspondents have written to enquire where they can procure tubers of this esculent for seed. They can now be had of Prince & Co., Flushing, N. Y., for $3 00 per hundred.

Chemicals.—"Nemo," writing from Quebec, wishes to know if there is a market in Canada for certain chemicals produced "from wood boiling," and what are the respective prices. We are informed by the leading wholesale druggists that there is here very little demand for them, and that the following are the prices: Sugar of lead, 15 cents per pound; acetic acid, 12 to 14 cents; acetate of lime, 6 cents; naptha, 12 cents; charcoal, 12 to 14 cents per bushel in lump, 20 cents crushed.

Drainage Act.—A correspondent wishes us to publish the Ontario Drainage Act; but as the details of the statute have already been given in the Globe, and as copies of the Act have been sent to the reeves of townships, and other officials throughout the Province, so that any one may have an opportunity of reading it for himself, it seems undesirable to republish the whole in these columns. But we shall be happy to answer, to the best of our ability, any questions in reference to special points about which correspondents may desire information.

Wind Power for Farm Use.—A correspondent wishes information concerning a description of windmill adapted for farmers' use in sawing wood, cutting fodder, etc, etc. There are many such mills manufactured in the United States, and they are extensively used on the prairies, where the wind has great away, and consequent power. It may be doubted whether such will answer here in Canada, except in very exposed situations. Farmers are usually so situated near woods that the wind passes high above them, and a very tall mill would be required to be of any use. There are, however, localities where such mills may be used to advantage, and our correspondent is recommended to apply to any of the windmill makers, who usually advertise in American papers, before attempting a home-made contrivance, which, from want of experience, may fail.

Canadian Herd Book.—A correspondent enquires whether a second volume of the Canadian Shorthorn Herd Book will be published shortly. We understand that early next year, or sooner should a sufficient number of entries be made, the second volume will make its appearance.

Crushing Bones for Manure.—One of our correspondents wishes to know the best way to crush bones on a small scale. The usual course adopted is to erect strong fluted rollers, so constructed that a succession of points come in contact with the bones, thereby exposing them to an immense pressure as the roller rotates. After being once crushed thus coarsely, the bones are passed through a finer set of rollers with smaller teeth or points mashing into each other; and when thus crushed into about half-inch size, the dust is sifted out, and the uncrushed portions passed through stones and ground like gypsum or plaster. Bones, to be at all efficient as manure the first or second year, must be ground very fine, the finer the better. Half-inch bones will remain many months in the earth without decomposition, and consequently the farmer using them often feels much disappointed in the utility he expected he should have derived from their use. Bones of half inch size are better adapted for those situations and uses in which advantage is sought from a very gradual decay, such as vine borders or the like. The process sometimes adopted, of pounding the bones, is altogether less efficient than the crushing action of properly constructed rollers.

The Canada Farmer.

TORONTO, CANADA, APRIL 15, 1870.

The Provincial Association.

At the last meeting of the Council of the Agricultural and Arts Association an animated discussion and somewhat warm expression of feeling were elicited by a communication from the Minister of Agriculture, reflecting on the expensive management of the Association, and proposing certain measures with the view of reducing this expenditure, suggesting, among other things, that the present Agricultural Hall should be sold, and the library and offices removed to the Parliament Buildings. This proposition, though ostensibly one of economy, was regarded as, in reality, the first step in a scheme to bring the Association and the Council under the more direct control of the Bureau of Agriculture, and as such was emphatically and almost unanimously protested against, though the further discussion and final decision of the Council on the matter were postponed to the next meeting.

We sincerely trust that the complete independence of the Association will be carefully preserved. Whatever errors there may have been in the past management of the funds or general business, the fault must rest with the farmers throughout the country if in future the management is not what it should be. They have the matter now in their own hands, and have only to elect to the Council competent men who will faithfully discharge their duties, to secure the just and efficient administration of its affairs. Whereas, if the control of such a valuable public institution should pass into the hands of Government, the probability is, let who will be in power, that its interests will suffer. The Minister of Agriculture for the time being will have received his appointment from political and party considerations, and will in all likelihood be totally ignorant of agriculture, and the wants of that large class of the people who are engaged in agricultural pursuits. Or should he, by any singular good fortune, be a fit man for the position, his tenure of office may at any time expire, and his good intentions prove abortive. The men whom the farmers, through the agricultural societies, elect to the Council of the Association will, on the other hand, be the *elite* of their own class, every way well qualified to represent their views and advance their interests. The well-being of the Provincial Association must assuredly be safer in such responsible hands than in those of the Government Bureau. This is the feeling, no doubt, of the agriculturists generally; they have confidence in the present members of the Council, and if that confidence should be misplaced, the elective constitution of the Board and limited tenure of office leave the remedy where it should be, in the power of the farmers themselves.

The Farmers and the Protectionists.

One of the shrewdest acts of the would-be "Canadian monopolists" has been their cunning device to draw the farmers into their net. Though the Protectionist orators of Toronto, while addressing a city audience, could only style men engaging in agricultural pursuits as "hewers of wood and drawers of water" as compared with those in the higher walks of life pursued by the operators in factories, still, before the farmer, they have another story to tell, and strive to gain his consent to their schemes by promising him Protection in the shape of a duty on foreign breadstuffs. Now, did it ever occur to the farmer how

much such protection would amount to, and what he would gain by it? Look at it even from the standpoint of the rankest Protectionist. Take flour for example. Against some $2,069,274 worth which we have imported from the United States, we have exported to the United States about $10,000,000 worth. Shut out $2,000,000 worth, and we still export to the value of $8,000,000 more than we consume. Now, if we did not produce enough flour for our own consumption, there would be a possibility of advancing the price of what we have by putting a protective duty on foreign produce; but so long as we export $8,000,000 worth it is the world's market and not that of the Dominion that must fix our prices. In other words, the Dominion not being able to control the world's market, the world will control the Dominion's. In the meantime, however, the duty on breadstuffs will have answered the purpose of the Protectionists in opening the door for class legislation, and schemers of all classes will be clamouring for Protection. Coal will be protected, cotton will be protected, woollen goods will be protected, this thing will be protected, and that thing will be protected, till the unfortunate farmer who holds the key—the balance of power—and who, in hope of gain opened the door, will find that himself and his interests have been completely trampled under foot and forgotten by the eager throng who are rushing in through it. His cost of living will be doubled or trebled. Every yard of cloth he uses, every farming implement he needs, every pound of nails he buys, in short everything he consumes, save that which he has to sell, will cost him twice or thrice as much as it formerly did. He will no longer be able to go into the markets of the world to supply his wants, but he must pay just what the monopolists of his own country choose to ask. Where is his refuge? He is "protected," not a bushel of grain can come into Canada without paying a heavy duty; but what does this avail him, when Canada cannot use all his grain, and he has to sell in markets where he is not allowed to buy, and where no protection can reach. His position is simply this. He is compelled to buy all his manufactures at inflated prices, while he has to sell at natural figures. It is as though we had a currency some twenty or thirty per cent. below par, in which the farmer must receive his pay for his produce, while he is compelled to pay gold for everything he has to buy for home consumption. Our inflation of prices for everything manufactured in the Dominion having cut down the purchasing power of gold, the farmer who would be compelled to purchase within the Dominion and sell outside of it would not need to be very acute to see that he was being grossly swindled by the workings of Protection.

Agriculture is, to use a common-place expression, the backbone of a new country like ours; it is the occupation of the masses, and to attempt to regulate its produce to the consumption of the people, would be as impossible as to regulate the supply of light and air. With manufactures, however, the case is different. Give a ring of manufacturing monopolists Protection, and they can wring from a country its last surplus dollar, without adding in the smallest degree to the welfare of any but themselves. The farmer with his outflowing produce brings in the gold of foreign countries, while the greedy monopolist, who dare not take his chance with the farmer in the world's market, stays at home, and parasite-like, grows fat off the industry and thrift of those "hewers of wood and drawers of water."

The Duty on Live Stock.

A memorial has been presented to the House of Commons from the Provincial Board of Agriculture, asking the Government to allow the importation of live stock designed to improve the breeds in the country; and Mr. Young, of Galt, moved a resolution to admit thoroughbred animals free of duty. The Finance Minister, however, declined to allow the resolution to be put, and, strangely enough, it was not pressed to a vote, although had it been, it would doubtless have been carried, or, if not, the farmers of the country would at least know which among the politicians were friendly towards giving even that very small concession to the needs of agriculture.

While our legislators have turned the cold shoulder to this very moderate demand, the Americans evince a different pirit, for a member introduced a resolution into Congress not long since, to allow of the free admission of all animals imported with a view to the improvement of the stock of the country, and it passed without opposition, and the matter was at once ordered to be taken up by the committee of ways and means. We do not know what ever induced our Government to place a duty on live stock at all, for while it has acted as a great drawback to prevent many from importing, by reason of the risk of forfeiture through some careless oversight or mismanagement on the part of Customs officials, who are generally the most supercilious and obstructive of any class of men, the revenue derived has been ridiculously small, the importation being as follows in 1868:

Horses, 26; duty collected, $390. Cattle, 2; duty $20. Sheep, 54; duty $54. Swine, 7; duty $14.

Contrast this with our exports of live stock for the same year, which foot up as follows:—

Horses, 7,005; cattle, 40,660; sheep, 97,406; swine, 10,710.

The tax on the importer of improved stock is the more unjustifiable if it be true, as we are informed, that numbers of hogs are imported free ("in bond" it is called) by pork packers, to be re-shipped as pork to Europe and the Maratime Provinces. Surely the enterprising farmer has a better right to this slight indemnity than the mere trader.

Note.—In the tariff published since the above was written, we are glad to find an exemption introduced in favor of animals imported for breeding purposes.

The Drainage Act.

The Commissioner of Public Works has issued certain circulars and forms, together with a copy of the Ontario Drainage Act of last session, with a view of obtaining information as to those sections of the country which may be benefitted by the provisions of the Act. A copy of these documents has been sent to the various Reeves of the Provinces, with a request that the forms may be filled up and returned to the office of the Department. Amongst the circulars issued is one requesting the Reeves to inform the Commissioner whether there be any flooded, wet or moist lands in the township over which each presides. A form is enclosed which, being filled up, shows the No. of the lot, the No. of the concession, the approximate number of acres, and the quality of the land that the Reeve deems to be within the meaning of the Act.

Another circular calls attention to the Act, a copy of which is therewith enclosed, as well as to the "Act respecting Public Works" of 1869, and directs that the Council of the Township should, in the event of an allotment of money being made for drainage in their Township, agree to provide by By-Law for the repayment of the outlay as contemplated by the Drainage Act. A form of note undertaking to pass this By-Law is sent with the circular, which has to be signed by the Reeve—in Council, we presume—and returned to the Department. It is intimated in the circular that "the report "and estimate for draining the lands can be "obtained, when prepared, on application to "the Department."

Notes on the Weather.

The past month of March has been one of exceptional character. The weather has been exceedingly cold and stormy, and the fall of snow has been, quite unexpectedly, great.

The mean temperature of the month has been 25°.8, which is 3°.8 colder than the average, yet 2°.7 warmer than March, 1869. The highest temperature was 44° on the 29th, the lowest, 5°.2 on the 3rd. There have been 4 clear days, 9 partially clear, and 18 overcast. The prevailing winds have been N. W., but there were 14 days on which the wind was from an easterly quarter. Very little rain has fallen, but the fall of snow has been 62.4 inches, being 52.1 above the average, and 47.4 more than March, 1869. The fall of snow the present winter has been 123.4 inches, or over ten feet, and this is ten inches in excess of any year recorded. The heavy storm of 26th and 27th gave a fall of snow of 25.5 inches, and as it was very wet and heavy, the quantity of moisture in that amount is far greater than would be in an ordinary snow-fall. It is yet too early to tell for a certainty what are the prospects for the coming crop of winter wheat, mostly hidden, as it is at the beginning of the present month, under the snow, but in some few places, where we have been able to observe the plants uncovered, they seem entirely killed out, probably from the effects of the hard freezing they got early in autumn. It is to be hoped, however, that the damage done is not so great as appearances indicate, and we shall be glad to get reliable information from different points on the subject as soon as the actual appearance and prospects of the winter wheat can be told with certainty.

Toronto Nurseries.—The well known and long established firm of George Leslie & Sons have issued their annual catalogue of fruit and ornamental trees and shrubs, bedding plants and flowers, &c., a list which seems to include everything in the horticultural department suitable to the climate of Canada. The pamphlet is prefaced by useful practical hints on transplanting.

Fleming's Sale List for 1870.—We have received a copy of this very complete list of flowering plants and fruit trees, comprising a large variety of dahlias, verbenas, fuchsias, geraniums, and other choice ornaments of the garden, besides a good selection of all the best grape vines and small fruits. We direct special attention to the various horticultural advertisements in the present issue.

Correction.—In the advertisement of Clarke's Patent Two-horse Iron Field Cultivator, which appeared in the last two numbers of this journal, the address of the proprietor should have been Hampton, not *Hamilton*.

Horticulture.

CORRESPONDING MEMBER OF THE ROYAL HORTICULTURAL SOCIETY, ENGLAND.

Prize Essay—Award.

To the Directors of the Fruit Growers' Association of Ontario.

The committee appointed to render judgment upon the essays on small fruits have had placed in their hands three essays with the following mottoes, viz:

First. "In labor there is profit;"

Second. "Whatever tends to promote production, increases the wealth of any nation;"

Third. "Poma mitis;"

and now beg to report their award.

In their opinion they are confined to the consideration of the two first mentioned essays, since the third, bearing the motto "Poma mitis," contrary to the resolution offering a prize to the best essay on the raspberry, blackberry, strawberry and currant, treats only of the strawberry.

After a careful perusal of the two essays first above named, the committee have decided to award the First Prize to the essay bearing the motto "In labor there is profit," and the Second Prize to the essay endorsed with the motto "Whatever tends to promote production, increases the wealth of any nation."

The committee desire to express their opinion of the great merit and excellence of the essay to which the first prize has been awarded, and earnestly recommend its publication and a careful perusal of it by the public.

We beg to submit this award.

Given at Hamilton, this 21st day of February, 1870.

W. H. MILLS.
ROBERT BURNET.
W. HOLTON.

Secretary's Report

To the Directors of the Fruit Growers' Association of Ontario.

Gentlemen,—I have this day received the award of the committee appointed to read the essays that had been received in competition for the prizes offered by this Association, and to adjudge the prizes; and therefore I have proceeded to open the envelopes endorsed with the mottoes to which prizes were awarded, and find that the envelope endorsed with the motto "In labor there is profit" contains the name of William Saunders, Esq., of London; and the envelope bearing the motto "Whatever tends to increase production, increases the wealth of any nation" contains the name of David Nicol, Esq., of Cataraqui, Kingston.

Your ob't. servant,
D. W. BEADLE,
Secretary to Fruit Growers' Association of Ontario.

Prize Essay on the Raspberry, Blackberry, Strawberry, and Currant

BY W. SAUNDERS, LONDON, ONT.

THE RASPBERRY.

Our improved varieties of raspberry have all originated from two or three wild native or foreign species—the European sorts chiefly from "the European Raspberry" (*Rubus idæus*)—our own from the common wild red raspberry (*Rubus strigosus*), and the black raspberry (*Rubus occidentalis*). These have been improved chiefly by cultivation, selection, and by hybridization or crossing. A number of plants have been raised from seed, and from these the most promising have been taken and cultivated; when fruited, fresh seeds have been obtained, sown, and subjected in turn to the same process of selection; or a hardy variety lacking flavour has been crossed with a tender high-flavoured sort, with the intention of raising, from the resulting seeds, plants inheriting the hardiness of the one, and yielding fruit possessing some portion of the delicate aroma of the other.

The soil best suited for the raspberry, and indeed for all the small fruits to be treated of in this essay, is a rich, moist, deep loam, inclining to clay rather than sand, well drained and thoroughly worked, either trenched with the spade or ploughed and subsoiled as deeply as possible. Such working, and, where the land has been at all previously exhausted, a liberal manuring, will place it in good heart to give strong growth to the plants placed in it. Individuals who are not favoured with such suitable soil may still grow good crops of fine fruit, even if the soil be very light and sandy; but in this case a far more liberal and continuous manuring will be needed, for the raspberry is a great feeder. It is useless to attempt to grow this, or any other of the small fruits we shall treat of, in a cold wet soil, for no amount of preparation short of thorough draining will remedy this defect.

With regard to the proper distance for planting, a difference of opinion exists; some advocating that the rows be placed four feet apart, others six feet or more. Where land is abundant, six feet, we think, is little enough, as this allows room for plenty of air and light, and also provides for horse-culture, which is a matter of considerable importance where a large piece is under cultivation. For similar reasons, in such a case we would advocate the placing of the plants four feet apart in the rows, rather than two, as this would allow of horse-culture the other way; for we are satisfied that there is nothing will tell so well on the health of the plants and abundance of the crop as a frequent stirring of the soil. Where land is scarce, as in the garden of the amateur, and it is desirable to crowd as much as possible into a small space, the rows may be reduced to three or four feet apart, and the plants from one to two feet in the rows, with fair results.

The red raspberry is propagated by suckers, which usually spring up in abundance from the roots of the plants as soon as they obtain good foothold in the soil. Some varieties sucker less readily than others—the Philadelphia, for example. Where it is wished to increase this propensity, a sharp spade should be thrust down into the soil all around the plant, to sever the roots, say a foot or less from the base of the plant, when the pieces of root thus cut remaining in the soil will usually throw up young plants in comparative abundance.

The black raspberries do not send up suckers, but are propagated by layering the tips of the canes. In the autumn the extremities of the canes lengthen much, become drooping and slender, finally touching the ground, and from this point sending out a mass of fibrous rootlets, soon developing, when undisturbed, into a vigorous plant; this, when well rooted, is severed from the parent by cutting the cane.

The spring is the proper time for planting. Then the well-rooted suckers or tips are dug up and transferred to their place in the new plantation, taking care not to expose the roots unnecessarily to drying winds or the heat of the sun. The rooted tips require no preparation in planting, but the stems of the suckers should be cut down within a few inches of the ground, so as to induce a strong shoot from the base for next year's fruiting. It is very unwise to attempt to obtain any fruit from raspberries the first year planted; with care a few berries may be ripened, but the fruiting process is an exhaustive one to the young plant, and it will often take years to recover from this foolish tax on its then limited resources. If the plants become well established the first year, a certain amount of fruit may be allowed the second without injury to the future prosperity of the plantation, but a *full* crop need not be expected until the third or fourth year.

Pruning.—Canes which have once borne fruit, bear no more. Hence, these should be removed assoon as the fruiting season is over, cut off close to the ground, so that the young canes may have more room and air. At the same time due regard must be paid to the thinning out of the new canes, removing all that promise to be weakly or slender. Since we depend on the strength of the current year's growth of wood for our next year's crop, any process which will conserve the vigour and concentrate the energies of the young plant is deserving of regard. Summer pruning and pinching we deem a valuable means to this end. The young plant, when it has attained about the height of three feet, should be pinched off at the tip; this will cause the side branches to develope, which in turn should be subject to similar treatment when from six to eight inches long. This pinching should be repeated if necessary, but should not be continued too late in the fall, since it would cause a late growth of tender wood which would suffer during winter. It might be practised safely enough till about the beginning of September, and any subsequent growth not wanted might be removed by a light spring pruning. This method we regard as much less wasteful than that of allowing the summer's growth to proceed unchecked throughout the season, and then prune back in the spring to a proper height. By this latter method the plant is allowed to waste its strength in the unnecessary production of wood which must be removed, and the growth is often long and slender; while in the former case all its energies are concentrated in the development of a stocky, well-ripened cane, far better fitted to bear its destined weight of fruit the ensuing season. This treatment is equally applicable to the Black Caps, unless where it is desirable to raise new plants; then the natural extension of the cane, or portions of it, must be allowed.

Manures.—It is universally conceded that stable manure contains all the elements required to recuperate the soil, stimulate the energies and increase the vigour of growing plants, and since this is probably readily obtainable by all our readers, we shall not enter into the subject of special manures. Stable manure should be well rotted before being used. If spread out in flattened heaps about three feet deep, in fall or spring, and turned over several times during the summer following, keeping it properly supplied with moisture, it will be in good condition in the fall to apply to growing plants, and a small quantity thus well prepared will be found more than equal in its effect to a much larger quantity of such as is coarse and only half decomposed. In this latter condition, however, it often serves a good purpose as a mulch to protect the roots either from the severe tax of a summer's drought or the pinching cold of winter.

Picking and marketing fruit.—Women and children are usually engaged in picking berries, and paid either by the day or quart, most commonly the latter; the price averaging about one cent per quart. The pickers take to the grounds with them the quart wooden boxes in which they are to be shipped, and when they are filled carry them to a shed, or other suitable place near by, where they are enclosed in well-ventilated cases, holding from thirty to sixty quarts. The pickers receive tickets corresponding to the number of boxes they bring in, which are produced when the time for payment arrives. All small fruits should be gathered carefully, free from leaves and other dirt, and also free from unripe berries. The pernicious practice resorted to by some of placing a few fine specimens on the top of a box while below the fruit is inferior, should be carefully avoided. Such a course disgusts both dealer and consumer; the surface should fairly represent the interior. In some localities where large berries are appreciated, it would doubtless pay to select the fruit, separating what is extra fine from the small and inferior; this applies particularly to strawberries. The latter would have to be sold at a reduced price; but the selected fruit would command a figure very much above the average, and the whole might thus be made more profitable. In all cases growers should avoid mixing their fruits; an assorted package, even if some of the varieties are superior, will seldom sell as readily as one the contents of which are uniform. All imperfect fruit should be rejected; half a dozen of such in a box will attract the attention of a purchaser far more readily than twice that number of extra good specimens. The best policy is to consign such to the pig-pen or the manure heap; reputation for quality is quite as valuable to the fruit grower as to any man in any other department of business.

Varieties.—These may be conveniently divided into three classes. 1st. Such red or yellow raspberries as are tender, and require winter protection; suited chiefly for amateur culture. 2nd. The hardy varieties, including some new ones claimed to be so, but as yet unproven in Canada. 3rd. The black raspberries.

Brinckle's Orange.—Of all raspberries we regard this as the finest. Its flavour, aroma, and appearance are equally charming and delicious. It is large, and of a beautiful orange yellow colour, and its full and slowly maturing crop supplies the table of the grower with a daily portion for three or four weeks. We think this variety might be grown with profit for a near market, but it is too soft to bear shipping far. In most parts of the country it would need winter covering; but in some of the more northern sections, where the snow lies deep and unbroken throughout the winter, if pruned low this would probably be a sufficient protection. In localities less favoured in this way, the canes might be allowed to grow moderately long, bent over as closely to the ground as possible without breaking, their tips covered with earth, and some loose litter—pea straw or light manure—thrown over them. The expense of covering an acre in this way would not be very great, and we think that the additional price the fruit would bring over any other variety would more than compensate for the extra labour.

Franconia is a large red variety of fine appearance and flavour, and very productive. In the milder portions of Canada, the Niagara district for example, it is hardy enough to stand most winters without injury, but it cannot be relied on in other sections away from the influence of the lakes. With me it has proved quite as tender as Brinckle's Orange.

Hornet—This is a still larger red fruit, very productive and of good flavour. Besides these we may enumerate the Fastolff Belle de Fontenay, Red Antwerp, French, and Marvel of Four Seasons—all good varieties.

We now come to the second class, embracing those which will endure uninjured the cold of winter without protection.

Philadelphia—Of all the hardy varieties this has been most widely tested, and maintains its character for hardiness and productiveness everywhere. It is dark red, medium to large in size, moderately firm, but very deficient in flavour, not equal we think in this respect to the wild fruit. We doubt very much whether this variety will pay for cultivation in localities where the wild fruit abounds, for although larger, it would necessarily be brought into competition with the native variety, and would hardly sell at a much higher price. A great deal would depend on how it was marketed.

Yellow Canada and Arnold's Red are two seedlings raised by Mr. Arnold, of Paris, Ont., which promise well. They are undoubtedly hardy, and are said to be very productive. They deserve fair trial, and we hope they will prove to be a valuable acquisition. Mr. Arnold merits great praise for his many efforts to improve our fruits.

Clarke—This new variety is highly esteemed in many parts of the United States on account of its hardiness, but we believe it has not yet been subjected to the test of our Canadian winters. The fruit is said to be large, light crimson, sweet and high flavoured. It is doubtless worthy of being tested.

Naomi—Much is said in favour of this new variety. In size and quality it is good, but it is doubtful if it will sustain the character claimed for it by its originators for hardiness.

Class 3rd—Black raspberries—The Doolittle Black Cap has been well tried throughout Canada, and has proved hardy and prolific. The berry is moderately large, black, with a slight bloom, sweet, juicy, and similar in flavour to the wild black-cap.

Mammoth Cluster, introduced to public notice by Furdy & Johnston, of Palmyra, N.Y., is doubtless an improvement on the Doolittle, being larger and more productive. We hope this berry will be extensively tried. Its period of ripening is just after the Doolittle.

Davison's Thornless is another new claimant for public favour, ripening about a week earlier than the Doolittle. The absence of thorns on the canes will be of great advantage in gathering the fruit.

Golden Thornless is a new yellow raspberry belonging to the same family, is nearly if not quite as large as the Mammoth Cluster, firm in texture, of handsome appearance, but deficient in flavour.

Although we have now enumerated many varieties, all of which possess some good points, we still feel that they all have their defects. We want a raspberry that will combine the good qualities—hardy, productive, large, juicy, moderately firm and high flavoured. Whether we shall ever attain to this degree of perfection, time alone will disclose. We sincerely believe it to be possible, and trust that the many labourers who are working to produce new varieties will never relax their efforts until something near this desired end is obtained.

Dr. Asa Gray, in his Manual of Botany, speaking of the black and red raspberries, says, "some curious forms are known, with fruit intermediate between these." We are not aware of any such in cultivation, but the fact of their being met with in a wild state would suggest the idea of a natural crossing of these two through the agency of insects. Might not some *valuable* varieties be similarly produced by the more intelligent workings of man? Here is an almost unexplored field for the enthusiastic fruit grower.

Insects—The raspberry is not without its insect enemies. A borer, the grub of a long horned beetle (*Oberea tripunctata*) burrows its way up and down the middle of the cane, weakening and destroying it. The beetle girdles with its jaws the new cane not far from the tip, in two places, one ring an inch or more below the other, and between these, in a puncture, the egg is deposited, which soon hatches into a grub, furnished with powerful jaws, and which at once enters on its destructive career. The tip above the upper ring on the young cane withers and droops, by which the presence of the enemy may be readily detected. The operations of the parent insect begin early in July, and continue for several weeks. By looking through the canes occasionally at this season, and removing all the withered tops, down to the lowest ring, this insect may be pretty well subdued, as it is never abundant. The worm lives in the cane, and undergoing its transformation there, appears as a beetle the following June.

A much more troublesome pest is the grub of the raspberry sawfly, a green worm covered with short green spines. This eats out the soft parts of the leaves, leaving the skeleton framework of tougher veins. There are two broods during the year. The fly deposits its eggs early in spring, on the under side of the young leaves, soon after they begin to expand, where they speedily hatch, and in a few weeks become full grown worms, about three quarters of an inch long. Entering the chrysalis state, just below the surface of the earth, they appear again by the middle of summer as perfect flies, deposit their eggs, and from these the second swarm is produced, the survivors of which pass the winter in chrysalis under ground. Hellebore is a sovereign remedy here; an ounce or so mixed with a pail of water and showered on the bushes with a watering pot makes short work of them.

The tree cricket (*Œcanthus niveus*) is another enemy—a green, active, grasshopper-looking creature, appearing late in the season and chirping merrily among the green leaves all the day. The female has a long ovipositor, which she thrusts more than half way through the cane, and by means of which she introduces her long yellow eggs. A row of these, placed closely together, and occupying perhaps an inch or more of space, so weakens the stem that it readily breaks from its own weight as soon as the foliage appears in spring, and thus the crop is lost. We know of no method of destroying these as ready as that of cutting the affected portions out and burning them some time between fall and spring. They are readily discovered, appearing as a short seam with little raised dots on it.

THE BLACKBERRY.

Much that has been said about the raspberry applies equally well to the blackberry. The methods of raising new varieties—the soil and its preparation, proper distances for planting, propagation by suckers, time of planting, pruning, and insect enemies, all apply here and need not be repeated. It remains then only to treat of the varieties in cultivation. These, like the raspberry, have originated from our wild sorts, of which there are five or six species.

Lawton or New Rochelle, a very large juicy berry, moderately sweet when fully ripe. This variety has been tried in many parts of Canada, and usually proved a failure. The canes will not stand the winter, and their growth is too robust and thorny to admit of their being laid down for winter protection.

Wilson's Early—A new variety, said to be hardier than the Lawton, a very large, oblong, oval, firm, sweet berry, ripening earlier than the other varieties—will be a great acquisition if it will endure our winters.

Kittatinny—Also recently introduced to notice, and reported to be very hardy. Fruit large to very large, sweet and firm, a good grower, very promising, and should be extensively tried.

Sable Queen—This fruit was first offered to the public last year; it originated in Massachusetts, where it has stood the winters for some years. The fruit is fine looking and will doubtless be widely tested.

THE STRAWBERRY.

All our large and luscious strawberries, which charm the eye and delight the palate, have had their origin also in the wild vines of the woods. These wonderful changes have been brought about, too, by selection and hybridization, man assisting nature, as it is always his happy privilege to do. New varieties have thus been multiplied rapidly, until now their number is almost confusing.

Soil such as has been described as suitable for the raspberry is equally good for the strawberry, for although the wild vines are often found luxuriating in arid sandy spots, yet no fruit shows in grateful growth a readier appreciation of generous treatment than the strawberry. The richer the ground the heavier the crop, is a safe rule to go by, to any reasonable extent.

The vines are usually planted in rows, two

three, or even four feet apart, with the plants set a foot apart in the rows. The wider distances are required when it is intended to use horse culture. The runners are cut off as fast as they appear, and the ground kept free from weeds. Before winter sets in, it is well to cover the entire surface with straw or other litter, removing it only from the crowns of the plants in spring, leaving it all on the ground until the fruiting season is over, as it will help to keep the earth moist and the fruit clean. After the berries are all picked, it will require removal and the ground well weeding and pulverizing, since it will have become very hard by the continuous tread of the fruit gatherers. The plants may be renewed after two crops have been taken by allowing the runners to spread over the surface, and plough under the old plants and nearly all else, leaving only a narrow strip of young plants every three or four feet. The ground after ploughing may be levelled with a cultivator.

The plants should be carefully set, not thrust into a hole with the roots compacted into a bundle, but in a natural position. Much of the success of a plantation will depend on proper attention to this point. Unless the vines can be got out quite early in the fall, so as to be well rooted before winter, we prefer spring as the season for planting. There is not much gained in point of time by late fall planting, and the plants are very likely to be injured by the severe frosts of winter.

Varieties—We think it is generally conceded that there is only one variety as yet in common cultivation which will really pay to cultivate for market purposes—that is, the Wilson's Albany. Every large producer in the country depends on it for his main crop. It is true, when compared with some other varieties, it is acid, and lacks flavour, but when well ripened it is not so far behind in these respects as some would have us believe. For our own part, we can eat Wilson's Albany, when we can get them, without making a wry face, and the general public seem to regard them with equal favour, judging from the immense quantities which ever find a ready market.

Many other varieties claim the attention of the amateur, some for their delicate flavour or aroma, others for their immense size, but none of them, in my experience, come near the Wilson for productiveness. The following list embraces nearly all of much merit:—Jucunda, Agriculturist, Bishop's Seedling, Nicanor, Charles Downing, French, Ida, Downer, Hooker, Green Prolific, Golden Seeded, Ladies' Pine, Russell, La Constante, Trollope's Victoria and Triomphede Gand.

The strawberry has not usually been much afflicted with insect pests. Occasionally the crop will be partially destroyed in some particular field by the ravages of cutworms, the caterpillars of some of our common moths or millers, or by the grub of the cockchafer or May beetle. But of late two new enemies have appeared upon the scene which demand a few remarks, since, should they become generally troublesome, the profits of the strawberry crop would be much diminished. One of them is a leaf-roller, a small green caterpillar which rolls up the leaves and fastens the opening blossoms into a ball with silken threads, and living within consumes them. These are the progeny of a small yellowish moth, who lays her eggs upon the plants quite early in spring, so that the caterpillars become nearly full grown, and capable of most mischief, just at the time when the plant is coming into full flower. On one patch we examined the past season the damage from this cause alone would be moderately computed at half the crop. We have also observed this insect in several localities on the wild strawberry. The other is a borer, the issue of a still smaller brown moth, who lays her eggs on the crown of the plant late in July or early in August, which soon hatch into small reddish caterpillars, which burrow through the heart of the plant in various directions, through the fall and winter, either killing it outright or weakening it so much that it sends up in spring only puny barren shoots from about the base. Late in May, when the leaf roller is active and full of mischief, this twin brother in the work of destruction sleeps quietly in chrysalis, appearing in the winged state about the middle of July. The following remedies are suggested—Dusting with fresh air slaked lime, or with soot, or watering with hellebore, mixed as for the currant worm These would certainly be of service, but whether they would singly or jointly entirely meet the case is a matter of doubt.

THE CURRANT.

Of these we have red, white, and black, varying in foliage and fruit and time of ripening, all requiring a rich soil, well worked and manured, to produce fine crops of large fruit.

They may all be propagated by cuttings, which are best made in the fall, tied in bundles and buried under ground during winter, and planted in spring. The young bushes of one to two years' growth should be planted out in rows, from five to six feet apart, and four feet in the rows. The pruning and management of the red and white currant is somewhat different from that required for the black. The fruit of the former is mainly produced on wood that is two or three years old, hence in pruning the new wood may be shortened considerably to induce the formation of strong fruit spurs; in the black variety the fruit is produced from one year old wood as well as from small spur-like shoots from the older, which should be borne in mind in pruning, so that a sufficient amount of wood of last year's growth be left to insure a full crop of fruit. In both cases a portion of the old wood should be removed from time to time, as well as some of the shoots or suckers, when they are likely to become crowded, so as to keep the head open and admit light and air to the centre of the bush. The stool or bush form is the natural mode of growth for the currant, and is less trouble, and, we believe, far better than the method sometimes recommended of growing in tree form with a single stock. The chief objection to the latter is that should the currant borer visit this single stem the bush is lost, for the small hollowed trunk would necessarily break from its weight of foliage.

Varieties—The following are some of the best in cultivation.

Red Dutch—Fruit large, deep red, rich and good, bunches long and tapering, a vigorous grower and very productive, an old and well known sort.

Victoria—Fruit large, bright red, acid, but of good flavour, bunches very long and tapering, very productive.

Cherry—Fruit very large, dark red, acid, only second in quality, bunches very much in size, this is the largest red currant in cultivation.

Versailles—Very closely resembling the Cherry, by some thought to be identical.

Prince Albert—Fruit large, bright red, rather acid, not rich in flavour, very productive, later than most of the other varieties, for which it is chiefly valued.

White Grape—Fruit large, yellowish white, transparent, juicy, moderately sweet and rich, bunches medium size, habit vigorous, very productive, the best white currant.

White Dutch—Fruit very similar in appearance and quality to the white grape, but somewhat smaller.

Black Naples—This variety has now almost entirely superseded the old English black. It is very large, black, sweet, with a peculiar musky flavour, bunches medium size, loose, a vigorous grower and productive.

Insects—There are several insect enemies, affecting chiefly the red and white varieties, with which almost every currant grower has to wage continuous battle, and so troublesome have they become of late that the culture of these valuable fruits has been sadly interfered with, many having given it up almost in despair. First in its destructive powers we would place the currant borer, a small whitish grub with brown head and legs, which lives in the stems of the bushes, burrowing up and down, making them so hollow and weak as to be liable to break with every wind. The parent of this worm is a pretty little clear winged moth (*Egeria tipuliformis*) something like a wasp, with three gold bands across its body. The moths appear about the middle of June, flying in the day-time only, depositing their eggs singly near the buds, where they soon hatch into small worms, which eat their way to the middle of the stem, and there enter on their career of destruction. When mature they are about half an inch long; they live in the stems through the winter, change to chrysalis early in the spring, appearing as moths in June again. These can best be kept within bounds by carefully removing in spring every stem found to be hollow, and burning it.

The caterpillar of a geometric moth (*Ethopia ribearia*) called a measuring worm, feeds on the leaves, when numerous stripping the bushes bare. Its colour is yellowish, dotted with black, with its sides streaked with white. It is about an inch long when full grown, and has its feet placed at each extremity of its body, so that in moving it loops itself up at every step. The moth from which this worm is produced is a delicate-looking creature, measuring about an inch across the wings, which are yellowish in colour, spotted with pale brown; the spots being arranged into one or two irregular bands extending across the wings. The eggs are usually deposited in May, but sometimes later. The worms are found during the month of June, and occasionally in July. The best remedies are hellebore and hand-picking.

The Gooseberry Saw-fly (*Nematus ventricosus*) also deposits its eggs on the currant leaves, and proves usually a much greater pest than the measuring worm. The perfect insect is a small fly nearly as big as a common house-fly, which appears early in spring, and deposits its eggs along the ribs on the under side of the new leaves as soon as they are sufficiently expanded. These speedily change to small green worms dotted with black, which at once begin to devour the leaves. They grow rapidly and are often so numerous as to strip a bush entirely bare in a few days. When fully grown they are about three-fourths of an inch long, and at their last moult lose their black dots, appearing in uniform pale yellowish green. They spin a small, tough, papery-looking cocoon, sometimes at or under the surface of the ground, at other times attached to the leaves or stems of the bush, from which the perfect insect escapes early in July. There are two regular broods during the season, and often a few odd specimens appear out of season, between times, so that constant vigilance is necessary to insure successful resistance to their repeated onslaughts. A ready means of destruction we have in powdered hellebore; an ounce of this well mixed with a pail of water, and applied with a watering-pot, clears the bushes effectually in a very short time.

A green worm occasionally affects the fruit, drawing the berries together in a bunch, fastening them with silken threads, and consuming their contents. This, however, is seldom met with excepting on the gooseberry, and needs only a passing notice. Where they prove troublesome we can suggest nothing better than hand-picking.

The Black-cap Raspberry seems to be a great novelty in Germany, and is now grown there with great success. Nothing was known of the fruit in that country until it was introduced from America.

Improvement of Native Flowers and Fruits

To the Editor.

Sir,—For years past I have been looking out for some articles or communications in our horticultural periodicals upon this interesting subject, and with the hope of inducing some young persons to enter upon this pleasing field of labour, I beg to offer a few remarks, feeling assured that no real lover of the beautiful who has strolled through our native forests in the summer season, can fail to have been struck with the beauty and brilliancy of our native flowers, and the rich foliage and frost-defying hardiness of our native fruits. In many of our town, village, and country burying grounds, what noble specimens of native flowers and fruits are frequently to be found. In a graveyard not far from where I write there is a neglected spot set apart for the interment of the poor and the stranger. Upon some of these graves there has sprung up spontaneously a luxuriant cluster of wild roses, with their roots running together in a thick entangled mass, and in the summer season, instead of there being a few straggling flowers, there is a perfect sheet of beautiful, though single flowers, and in the fall an abundance of fruit for the birds. Not many rods from this are the graves of persons of wealth, where many exotic flowers are planted, and cultivated every year at considerable expense. Here, for instance, stands the rose "Giant of Battles," but the poor giant is a dwarf beside the wild roses, and is every winter cut down to within a few inches of the ground by frost, while the wild roses have stood there for years, bidding defiance to twenty degrees below zero, with no cultivation or protection whatever.

I was very highly pleased with the article in your columns in February, from that veteran florist, William Paul, of Waltham Cross, England, and hope every lover of his country amongst us will see it and read it thoroughly, and then transfer the instructions there given on crossing plants in England to our own indigenous flowers. It will be well also to look around and see if there are not many things besides those that are valued for their flowers only, to which these instructions will apply. Consider, for instance, our numerous native nut-bearing trees, and say can these not be improved by crossing with some better European varieties. Look again at the various members of the cotton family that spring up spontaneously in many localities in this northern portion of America. I ask can these not also be crossed with the cotton of the south, and yet preserve the hardiness of the one with all the good cotton-yielding qualities of the other? I feel confident they can.

The greatest difficulty that stands in the way of these improvements is to find men willing to devote their time and means to this purpose. Perhaps it may be just as well to look some of the discouragements to this undertaking in the face in the outset. One of these, and perhaps not the least to some sensitive persons, is a class of jealous, narrow, contracted little souls that will meanly insinuate that we are prompted by no higher motive than a desire of pecuniary gain. Of this class of persons I would say, let them alone, and rest assured that when the improvements suggested shall become a reality (which they most assuredly will if persevered in) these dog-in-the-manger men will be the loudest in their acclamations of praise, provided they are only allowed a share in the honours.

I have long been of opinion that in whatever country nature has planted varieties of any of her numerous orders of plants, there, that family, by judicious crossing, and proper cultivation, can be raised to a high degree of perfection. That the improvement will be attended with some difficulty and much labour and expense there is no doubt, but if the one hundredth part of the money that has been spent these last twenty years in procuring useless varieties of fruits, flowers, cereals and vegetables from Europe had been spent in improving our own native or acclimatized ones, horticulture and agriculture in Canada would occupy a much higher position to-day than they now do. Not that I would discourage testing the productions of other countries by any means, but it would be folly to deny that ninety-nine out of every hundred of the fruits, flowers, cereals and vegetables that succeed well in the British Isles, when planted in Canadian soil and climate are a total failure.

CHAS. ARNOLD.

Paris, Feb. 24.

How to Prevent the Attacks of the Apple Tree Borer.

At about the end of May or the beginning of June, according to the warmth of the weather, the winged beetles of the Apple Tree Borer begin to deposit their eggs on the bark of the tree. They do this at night, depositing only one in a place, selecting sometimes the forks of the main branches, but more commonly the trunk of the tree near the ground.

If, then, at about the first of May the whole of the trunk of the tree, up to and including the forks of the main branches, be thoroughly washed with cold-made soft soap, or well covered with whitewash, or even well washed with a solution of potash, the alkali will kill the eggs, or the young grubs as soon as hatched, if the female insect should chance to deposit them on the tree. But insects are all endowed with most wonderful instincts, and it is very doubtful whether the parent beetle ever deposits her eggs on a tree that is thus covered with a strong alkali. Those who have tried this preventive unite in saying that the trees thus treated are never attacked by borers of any kind, but remain sound and safe.

How to Destroy Bark Lice.

As a usual thing these insects are most abundant on unhealthy trees, but sometimes the tree might recover were it not for the debilitating effect of these insects. In some parts of the country there is considerable complaint of these bark lice, and it is quite possible that they should fasten upon a healthy tree in such numbers as to seriously impair the health of the tree.

When they are not very numerous, a wash of cold-made soft soap, or of a solution of potash, or even a thorough white-washing with lime white-wash, will be found quite sufficient to rid the tree of their presence. But when they have become very numerous, it has been found to be more surely destructive to prepare a mixture by boiling leaf tobacco in very strong lye until it is reduced to an impalpable pulp, and then mix it with cold-made soft soap until it is about as thick as good paint, and then put it on with a paint brush to every part of the tree, trunk, branches, limbs, and twigs, quite early in the spring, before the buds are much swollen. This application, if thoroughly put on, will surely be the death of every bark louse.

Fruit-growing in the Ottawa Region.

The report of the Fruit Growers' Association of Ontario contains a summary of the information obtained from the counties of Renfrew, Carleton, north part of Lanark, Russell and Prescott, from which we learn that the apples to be planted there should be of the most hardy kinds, such as the several varieties of crab-apples, the Snow-apple, Duchess of Oldenburg, Red Astracan and Northern Spy. The Baldwin and Rhode Island Greening are spoken of as being too tender, the trees being often winter-killed, or so injured by the severity of the climate as to fall easy victims to injurious insects.

Pear trees have not succeeded well, on account of the extreme cold. The varieties which have in some measure succeeded are the Flemish Beauty and Stillwell. The latter named variety may be some local sort that has been found to be worth cultivating on account of its hardiness, but it is not described or named in American pomological works.

The plum tree seems to endure the climate somewhat better, and in some seasons bears immense crops of fruit. The black knot is troublesome there, as almost everywhere else. The curculio too is found there, stinging the fruit and causing it to drop off before it is ripe. In some seasons the fruit seems to burst after it is set, swelling out into a mere puff ball and then dropping off. Yet, after all, it seems to be fully as reliable as any of the fruit trees.

Cherries, particularly the sweet varieties, do not endure the climate; the Red Kentish is grown to some extent, and there are wild varieties.

The peach, quince, apricot and nectarine cannot be grown.

The small fruits have not received much attention. Strawberries, raspberries, and currants will all thrive well, and bear fine crops of fruit. Blackberries grow wild in great abundance. The English gooseberries, on light, sandy soils, mildew badly; less on low, heavy land.

Grapes have not been tried to any extent, and there is much confusion and contradiction in the information concerning them. It does not seem to be possible that the Isabella and Catawba should usually ripen there, yet such is the testimony of one gentleman. We must wait for further experiments.

The soils best suited to fruit trees are those that are lightest and warmest. All attempts to grow orchards on clay land have been unsuccessful.

Protecting Trees from Mice.

To the Editor.

Sir,—Can you inform me if there is any efficient method of preventing the destruction of young apple trees in the winter from mice girdling them? I have stamped the snow down around them several times this winter, and yet I now find that several valuable young trees in bearing are completely girdled upwards of a foot from the ground. I have in vain tried to trap the mice. Would painting the trees in the autumn with some liquid be of any use, say tar? or would the application injure the trees? I find some pear and apple trees of three inches diameter utterly destroyed.

HENRY BORINGEARTH.

Reply by Hort. Editor.—If a cone of earth is raised around the trunk of the trees to such a height that the top of the cone will be above the snow, the mice will not girdle the trees, because they always work under the snow. This cone of earth must be placed around the trees early in the fall, before the ground freezes. If the snow usually lies too deep on the ground to admit of such a cone of earth being raised around the trees, then the trunk may be covered with sheets of brown paper tied on with a string to a height that will be above the snow line, and then coal-tar painted on the brown paper. The direct application of the coal-tar to the trees has been found to be injurious to them. If coal-tar can not be had, the paper may be painted with any cheap paint and sanded while the paint is wet. The paper should be stout enough to admit of being painted.

Trimming Hedges.—"Neseius" asks what is the proper time for trimming certain kinds of hedges. Buckthorn, Hawthorn, Privet, and Honey Locust require to be trimmed in April and July in order to be neatly kept; the Sweet Briar only in spring; and the Norway Spruce should be shortened in with the knife, not trimmed with the shears, in the early part of June.

Packing Apples for Long Voyages.

Those who read the discussions on the packing of apples, at the last meeting of the Fruit Growers' Association, will remember Mr. Ball's statement of his method of packing, and that some gentlemen thought that he did not press the fruit in sufficiently tight. We have been privileged to see a letter to Mr. Ball from his consignees in Scotland, dated February 3rd, 1870, in which they say, "Your good and honest packing is a great help to us, and indeed we would rather want apples entirely than have barrels good only on the top, and unfair and even bad below, as some ship them. It it our custom to refer to your careful packing and your honest packing as a model to all others. The barrels open as good and *tight* as when they left your store. Please on no account remit your vigilance and care."

From this it will be seen that Mr. Ball's mode of packing ensures the safe arrival of the fruit, and that they are pressed down sufficiently tight for all necessary purposes.

But we have craved the privilege of making these extracts from the letter, not merely to show that by his method of packing the fruit is kept in good order, but chiefly to impress upon our fruit growers the importance of carefully selecting their fruit, and never allowing any of inferior quality to get into the barrels. The attempt to put off an inferior sample by mixing it in the body of the barrel with fine fruit is sure to be detected, and to be visited upon the dishonest packer in the end.

The New Rose—Madame La Baronne de Rothschild.

We have just been favoured with the privilege of seeing this truly superb rose, which was imported from England last autumn and bloomed in the house. No wonder that it received a first-class certificate from the Royal Horticultural Society, England. In habit the plant is very robust, and judging from the number of buds now formed and forming, it should be a free bloomer. The colour at this time is a most beautiful clear deep rose, and the flower large and double. This rose has the reputation in Europe of being one of the best, if not the best, of its colour.

Currants and Gooseberries.

A fruit seller of New York City, writing for the *Rural New Yorker*, calls attention to these fruits on account of the ease with which they can be cultivated and marketed. Gooseberries sell in that market at from three to five dollars per bushel. Currants sold last year at from ten to fifteen cents per pound, commanding a ready sale at these prices. They can be shipped in grape boxes with entire safety, and arrive in good order. Will some of our readers residing in the cities of Ontario inform our readers whether these fruits command a ready sale with us, and what are the ruling prices in Toronto, Hamilton, London, etc?

Double Geraniums.

We have been so much pleased with these great acquisitions to our summer flower beds that we have had an engraving made of a flower truss, in order to give our readers some idea of what exceedingly beautiful things they are. The engraving is about one half the natural size.

These double geraniums possess the advantage of holding their bloom much longer than the single varieties. In some the flower truss is remarkably large, containing from sixty to eighty blossoms, and in colour as rich as a Provence Rose. Gloire de Nancy is of a rosy carmine, Le Vesuve is an orange scarlet, Madame Lemoine is a bright rose colour, Victor is bright orange scarlet, striped and flaked with white, and Victor Lemoine is of the finest scarlet. These varieties are now grown in Canada, and can be had of our nurserymen and florists.

The Concord Grape.—A correspondent of the *Rural New Yorker*, writing from Montgomery county, New York, says that the Concord grape stands first, is hardy, well adapted to our severe winters, bears full and ripens early. The Isabella is too often cut off by the early frosts to be reliable.

Tomatoes.

A correspondent of the *Rural New Yorker* states that he has found these plants grown in boxes in the kitchen window and transplanted a few times, though only a few inches high when set out, would ripen their fruit quite as early as large plants of the same variety, grown in pots and purchased of the market gardeners. He therefore concludes that age, not size, is what is wanted.

He also states that he has grown, with much care, many varieties, and has found the Eureka and Keyes' Prolific ripen first, and the Early York and Tilden follow, while but very little behind either of these comes the Large Smooth Red, a variety much to be preferred every way for a general crop. He would give the preference to the Tilden but for its uniform tendency to crack. Lester's Perfected is the latest in ripening of any of the sorts he has cultivated.

Our own experience of last summer leads us to expect that the General Grant will prove a formidable rival to the Large Smooth Red. In solidity, flavour, and early maturity under unfavourable wet cold weather, it excelled even the Large Smooth Red, which has hitherto been our favourite variety. But the experience of one season is not sufficient to establish a reputation over one that has been so long tried and found to be reliable.

Trees for Shelter.

To the Editor.

Sir,—In the January number of the Canada Farmer there is an article on the Norway Spruce, Now, as I have experimented a good deal in a small way in planting the "Greenwood Tree," perhaps you will give space for a few lines on my experience. The Norway Spruce is a noble tree, and if transplanted young, after the first two or three years grows very fast and is quite hardy, and if allowed plenty of room makes a very handsome tree. I planted mine in land trenched about eighteen inches deep, and as they were not numerous I took great care of them the first year, watering and mulching, and so lost none of them; I only have some two dozen altogether. I gave them an application of black peaty soil mixed with good fresh house ashes the second year, which they seemed to approve of highly. I have also some Canadian Spruce, almost, if not quite, identical with the Norway kind, and, I think, just as handsome. The "Norways" were got at Guelph nurseries; the "Canadians" in the bush. I have also a good many Balsams from the bush, and I really think they are as handsome as the Spruce. The Cedar is a good tree either for ornament or shelter, and is all the better for being clipped. The Tamarac, or Larch, is a very pretty tree, and is hardy, but likes moisture. Clipping improves it also when young. I had some in rather dry spots, and the hot, dry summer of 1858 killed several of them. None of my planted trees are over twenty years old. Some years they threw out leaders from twenty inches to two feet long, but in 1859, the year of the dreadful summer frosts, they hardly grew at all, and the pretty shoots of June were hanging in October like brown tassels. The Hemlock is the most tender of the Canadian evergreen trees, which is a great pity, as it is a beautiful tree, very like the Yew tree; it does not bear transplanting well, and the field mice girdle it when young. I cannot see your objection to calling a Spruce a *Fir*. In Scotland it was called a Fir, and the Silver Fir and the Scotch Fir, the handsomest, or grandest rather, of the whole lot. Pine may be more fashionable, and I went to see a beautiful *Pinetum* in Gloucestershire some ten years ago. The Latin names were there, of course, which about one in every fifty understands, but there was the "Scotch Fir," "Silver Fir," "Spruce Fir," and so forth, on the labels as well as the Latin names.

I got a belt of evergreen trees planted in the grass. At least the half of them died, but the rest are thriving nicely now, and some of them are large handsome trees, all Canadian from the bush. I have seen the Canadian Spruce used for a hedge, and it does very well. With regard to ornamental hedges, the common purple lilac makes a capital hedge. It is the first shrub almost to grow green in Spring, and keeps green till the snow falls, and a lilac hedge in full bloom is something worth seeing as well as smelling. The lilac

will grow anywhere; in fact, you cannot kill it, and it is a strong, tough bush. The cows eat the shoots when tender, but a summer's rest will more than make up the damage I would not like, however, to trust it by itself, or indeed almost any other hedge, as the cattle are very troublesome, and when annoyed by flies, I have seen them rush into a good big thorn bush just for the sake of a good scratching. If you wish another yarn on trees I will be happy to give you one; all I give is from my own practical experience.

Fergus. F.

Note by the Horticultural Editor.—Our correspondent "F" will please continue his very interesting letters. Actual experience is what is wanted; the success or failure of an intelligent planter is a guide to others. Does the Hemlock suffer from the severity of the winter at Fergus, or is the tenderness only the difficulty of transplanting? If the latter, that can be obviated by taking very small plants from the forest, and planting them in nursery rows, and shifting them two or three times before they are finally planted.

The objection to calling a "*Spruce*" a "*Fir*" is just the confusion that arises when one name is applied to two things that are really different. Botanists have classified the evergreens under the genera of Pines, Spruces, Hemlock Spruces, Firs, Cedars, etc. Now, if a correspondent calls the White Spruce the Fir, a reader is misled, and applies what is said to the wrong tree. There is need, therefore, of care to give the correct name of the tree about which we are writing.

Will not our correspondent plant out a Pinetum of such evergreens as promise to endure our climate, and give the results of his experiments to the public? We promise him much pleasure in the care of them, and such aid as it may be in our power to give.

Grape Queries

To the Editor.

Sir,—Would you allow me to answer several questions through the medium of your widely circulated journal? Many persons have written to me for information about grapes, asking what kinds to plant, &c. It would be difficult for me to write to every one, and so, if you think the following hints and suggestions of sufficient interest, you can publish them:—

1st. Which are the finest and showiest grapes for exhibition?

The largest and finest-looking grapes of my collection of seventy varieties is the Ontario. I have grown them three and a quarter inches in circumference to a single berry. But in my vineyard of seven thousand vines I have not a single Ontario, because it is too tender. The Ions also is a large and showy cluster, and Allen's Hybrid is also a large and beautiful cluster. These three are all magnificent-looking—black, red and white.

2nd. Which is best for market? This is a difficult question. I would give five thousand dollars to-day to know for a certainty which three kinds of grapes to plant to make the most money out of them, in a space of say twenty years. However, we are learning in the school of experience in this matter, and some of us have had to pay pretty dearly for such learning. I have had my twenty years of experience, and have about concluded that of the older and tried sorts, Concord and Delaware will give you most money. As to the new sorts, if I were to advise your readers to plant any of them, I am sure that fifty others, of perhaps equal opportunities to judge, would certainly differ from me, and so I say, try for yourselves.

3rd. Can we not grow a few of the finer foreign sorts—say Muscat of Alexandria, or the White Nice—in Canada, if we put them on the south side of a wall or building, and protect in winter?

I reply that I think it of little use to try; better try the natives out of doors; put your foreigners in the hot-houses.

I will note a few of our new grapes now before the public, but caution your readers to remember that their trial has only been for a short time, and in my own locality:—

Iona—Seems quite uncertain: sometimes fine, but generally does not ripen.

Creveling—*Of* first quality, and will surely ripen in Canada every season. Its great fault is that it generally gives poor clusters, but the berries are large.

Rogers, 4, 15, 19—General character very much like the Creveling.

Hartford Prolific—Very early; will always ripen in Canada; rather coarse quality, and in wet seasons drops from the bunch.

Israella—Very fair and early; not as strong growers as the others mentioned above.

4th. Where can we get good vines?

We have several good nurseries in the Dominion. I think all the varieties I have mentioned could be bought of any of our nurserymen or vineyardists.

J. C. KILBORN.

Beamsville.

Best Method of Training Apple Trees in Cold Climates and Exposed Situations.

It is said of Dr. John A. Kennicott, that no man has ever yet lived who had as good a knowledge of the form of tree that was requisite to enable it to withstand the great extremes of temperature, and the cold, bleak winds that prevail on the prairies of the West, and he said that the very best protection to an orchard on the bleak prairies is to make the branches low down, so as to cover up the entire trunk of the tree until the rough bark is formed.

These views of Dr. Kennicott are not without confirmation by observing fruit growers in our own Ontario. Mr. John Fisher, of the Township of Plympton, County of Lambton, says in a letter to the Secretary of the Fruit Growers' Association, written in 1862, "trees that are allowed to branch out low, say about three or four feet from the ground, are generally healthy, but those that have a long trunk are sure to get black on the south-west side, and soon die off"

Mr. L. Crosby, of Markham, in the County of York, writing about the same time, spoke of the importance of protecting the trunks of the trees.

Have any of our readers seen any orchards in the colder parts of the Province which have been trained with low branches? If any know of such, and can state the effect, beneficial or otherwise, we should be most happy to receive their communications. There is much need of some protection to the trunks of the apple trees in cold and exposed places. How best to secure that protection is a question of absorbing interest to all fruit growers whose lot is cast in the bleak parts of the country.

What Causes Failure of the Peach Crop?

To the Editor.

Sir,—You have frequently asked me to give you the result of my horticultural memoranda, if anything struck me as likely to be useful to the enquiring horticulturist.

For some years it has been a disputed point as to what affects the peach crop. My own conviction inclines to the degree of cold. Others, however, are in favour of the destructive influence of storms forming a crust of ice on the tree, and thus destroying the germ.

For the purpose of ascertaining if my theory were the correct one, I have kept a memorandum of the weather and the peach crops for many years, and I have invariably found that when the thermometer goes below 10°, the peach *blossom* bud is destroyed; the *leaf* bud appears able to resist a greater degree of cold, or the trees themselves would be killed. I have also found that the mere fact of ice forming on the trees does not affect them without the degree of cold necessary to kill the bud, which I contend is 10° *or below* For instance, in 1862, on the 15th March, we had a very remarkable storm of sleet, forming ice one-half to three-quarters of an inch thick on every limb and twig, causing great destruction amongst all trees and shrubs. My old peach trees were nearly all broken down. This, I find, on referring to my memoranda, was a "remarkably fine fruit year; peach trees full of fruit." In February, 1869, we had a similar storm, but not so violent. Last year, although not a good peach year, "the crop was very fair." If we have a good crop of peaches the coming season, I think the question will be pretty well settled; and I also think that if you would call the attention of the horticultural world to a discussion of this question, it will settle another question, as to what degree of cold the peach will bear without injury.

Would it not be a good subject for discussion at a meeting of the Fruit Growers' Association?

JAMES TAYLOR.

St. Catharines, March 2, 1870.

Lombardy Poplars for Wind-breaks.

To the Editor.

Sir,—Mr. Mitchell states that Lombardy Poplar is one of the best wind-breaks for an orchard. I question the propriety of planting wind-breaks for orchards. It takes five or six years before it is of sufficient height to protect anything; by that time the apple trees are large enough to take care of themselves. When bearing, if well sheltered, the buds will open early in spring, and the young fruit will be cut by the frost and spoil the crop; whereas, if not sheltered, the buds would not burst before all danger of frost is over. Mr. Mitchell will find that twenty-five feet would not prevent the roots of his poplars from reaching his apple trees. I have seen the row of trees adjoining the poplars droop and die, in consequence of the poplars' roots exhausting the soil. I would recommend Mr. Mitchell to use the plough to cut the roots off the poplars, or otherwise he will find that they will rob his apple trees.

R. H. SARVIS.

Hibbert.

Note by Ed.—If he does run such a furrow, and cut off poplar roots of any size, he will surely have a row of young trees come up in the furrow, for every broken root will throw up sprouts.

Evergreens for Farmers.

It is a fact which ought not to be, that more evergreens are planted in our villages and cities, than in the country by farmers. The evergreen is essentially a protective tree against cold and wind, more becoming in winter than summer, and in proportion as the weather is severe and the aspect of the landscape bleak and forbidding, does its presence add comfort and cheerfulness. About country places, in northern latitudes, where there is ample room for both deciduous and evergreen trees, hardly too many of the latter can be planted. They should be freely set in lines about the grounds of the dwelling, the outbuildings, garden and orchards, to form wind-breaks, and add warmth, shelter, and a snug, cosy look to the scene in winter.

Where shelter is the main object in view, and the planter is not cramped for space, a belt should be set, at least one rod wide, and in many situations large groups could be formed with the best results. For every purpose and situation there is no other evergreen which equals the well-known Norway Spruce. Although it is one of the giants of the forest in a state of nature, yet this species bears pruning, and may be relied on when planted thick and sheared into hedge form. For wide belts and groups the Scotch, White, and Austrian Pines are likewise excellent.

Success in growing a fine hedge depends very much on making the right beginning. Trees of nearly even size should be selected, although some irregularity may be corrected by after pruning. The lower branches should lie upon the ground. No after treatment can remedy the defect of a naked trunk. They should not be too large, and great care should be taken to keep the roots intact and from exposure to sun and wind. From the middle to the end of spring is the best time of the year for transplanting.

Another very important use of evergreens in the country is to form barriers along the sides of roads that are liable to be filled with snow-drifts. A double line of trees, set five or six feet apart in the row, and the rows placed half a rod asunder, would, in five years, afford complete protection against drifting snow. Railroads might be cheaply and most effectually barricaded against drifts in this manner.—*Rural New Yorker.*

The Filderkraut Cabbage.—James Vick says that no cabbage with which he is acquainted has given such general satisfaction as the Filderkraut. It is very conical or "sugar-loaf" in form, is very solid, and keeps well. It forms a solid head even under unfavourable circumstances, and scarce three plants out of an acre fail to make a fair marketable head.

Davidson's Thornless Raspberry.—Mr. H. Collins, writing to the *Gardeners' Monthly*, says that the fruit of this variety is large and fine, earlier than the Doolittle, matures its whole crop, while the later berries of the Doolittle are so small and dried up as not to be worth picking, and that the comfort of picking from plants that are free from thorns is no small consideration.

The Slug which appears on the leaves of the pear, plum and cherry, usually on the upper surface, can be easily destroyed by dusting the tree thoroughly with slaked lime or unleached wood ashes, as often as the slugs make their appearance. Indeed, the dry dust from the surface of the ground, if thrown with a little force upon them, will usually kill them.

The Logan Grape.—It bears full and ripens, colouring the earliest of any grape I have. It is not as sweet as some, but in view of its hardiness, and the fact, too, that the fruit is not injured by light frosts, I cannot but regard it as a valuable variety. It bears the winter well. Still, the hardiest here needs some protection in cold weather, at least laying down and being kept close to the ground.—M. Quinby, in the *Rural New Yorker.*

Tomatoes.—Sow in boxes of about two feet by one and a half, and six inches deep, in earth of the richest kind. Cover the seed half an inch deep. If you have a hotbed, place this box in it; if not, set it in a warm room, near a sunny window. Water occasionally. When the plants are an inch or two high thin them out to about an inch apart. So soon as the weather is free of frost, transplant in moderately good garden soil, not rich, as that would make fine vines, but poor fruit.—*Rural New Yorker.*

Grape Vines and Pear Trees in Enfield, West Riding of Middlesex.—I have a number of grape vines in cultivation, principally Clinton and Delaware. The Clinton has mildewed as well as the Salem. The others have so far kept healthy, contrary to what is generally reported, that those of the Labrusca species are most subject to mildew. The pear blight with me affects only some kinds, the others are exempt. The Tyson invariably blights very badly, while the Flemish Beauty, although only twenty feet from the Tyson, is as healthy and thrifty as a Lombardy Poplar.—W. G., in *Fruit Growers' Report.*

New Rose, Princess Christian.—This has received three first class certificates during the year 1869, from the Royal Horticultural Society, Royal Botanic Society, and at the Crystal Palace Rose Show, and has been thought worthy of a coloured plate in the *Florist and Pomologist* for January, 1870. It is described as being a very large flower, globular in the bud state, and finely cupped when expanded, the colour ranging from deep salmon to rosy peach, according to the age of the flowers, and holding on clear and bright to the last. It blooms continuously and abundantly from June to November, is robust, and of a hardy constitution. It is introduced by Mr. William Paul, of Waltham Cross, near London, England, and will be sent out by him this spring. We hope our rose fanciers will keep their eye on it, and that we shall soon have the pleasure of seeing it in Canada.

Apples in Gilford (South Riding of Simcoe).—Mr. Thomas Maconchy reports that the American Golden Russet and the Roxbury Russet bear well; that the Baldwin and Colvert, both as standards and dwarfs, are very fine; that the Duchess of Oldenburgh and Early Harvest do very well; the Spitzenberg and Snow apple are good, and Gravenstein very good; the Keswick Codlin is prolific; the King of Tompkins is very fine—extra; the Pomme Grise a shy bearer; Northern Spy very good; Primate good and bears well; Red Astrachan very fine; R. I. Greening pretty fair, and St. Lawrence very good.

The Best Summer Apple.—At the winter meeting of the Western New York Horticultural Society, the Red Astrachan was proposed by several of the most distinguished horticulturists as the best summer apple. A few of the members objected to it on the ground that it did not ripen its crop at one time, but extended its period of ripening over several weeks; while others valued it on that very account, its gradual ripening enabling them to market all the fruit without occasioning a glut in the market. The fruit dealers spoke of its handsome colour, which made it sell well; a few complained that the fruit with them was imperfect. F. R. Elliott, of Cleveland, Ohio, said it was one of the best market varieties at the West. We believe this variety succeeds well in all parts of Ontario, particularly in the colder parts, and on clay soils, and is one of the best, if not *the best* summer apple we have.

Apiary.

Bees, their Nature and Habits.

ARTIFICIAL IMPREGNATION.

According to a promise made in my last, I now publish what is claimed to be a new discovery for securing "artificial impregnation," in other words, a method whereby a queen may be caused to mate with selected drones. I give the method or experience of Mr. Freeman Moore, as written by himself, and published in the *Bee-keeper's Journal*, reserving any further comments of my own. He says:—

"I suffered great loss of time and sad disappointments in having my young Italian queens mate with the black drones of my neighbours, thus producing a hybrid progeny, which was, of course, worse than useless to me, and I resolved to try some plan whereby my young queens might be fertilized by drones of my own selection. Various were the plans I tried, but all failed, except in one instance, when I had a young wingless queen fertilized by one of the many experiments I subjected her to; but as I saw no evident signs of fertility at the time, I released her into a well stocked nucleus, and set about inventing some other plan. After trying various contrivances, of no importance, as I have since learned, I opened the small box containing this invalid queen, and to my surprise, she had filled nearly all the cells in a central card of worker comb. I carefully examined and found the eggs regularly deposited in the cells, and not having the appearance of being deposited by a drone-laying queen. I carefully closed the box to await the result, and in twenty-one days worker bees emerged, and none but workers. This now convinced me that something new was to be learned, yet I was but little better off now than at first, for I had no idea which plan was the successful one. One thing I could rely on was, that this circumstance proved beyond all doubt that it was possible to fertilize queens in confinement, even if they were hatched without wings. That I stood alone in this discovery I had no doubt, for long since it has been publicly taught and admitted as an established fact, that young queens are fecundated only on the wing high up in the air, and all imperfect ones that cannot fly are incapable of impregnation. About this time, through some correspondence with Mrs. Tupper, she informed me that she had also for years been trying similar experiments, with very satisfactory results. This encouraged me to make known to her the results of my experiment, asking her counsel and aid in fully developing this new theory. My first experiment was as already related; the second was precisely the same as Mr. Henry Atherton had related to me some years previous. I will give his own account in substance."

'I purchased a colony of bees that had swarmed twice, and on examining the second swarm, found three or four young queens during the process of hiving. I caught one of them, put her into a tumbler, set it in the window, where the sun shone nicely, and as I concluded she would be lonesome alone, I caught two drones because they could not sting me, and put them in the same tumbler with her. Almost as soon as I released the drones (he said with an oath) the queen fell on one of them and instantly stung him to death.' I remarked that this certainly was a mistake, as they never used their stings except on rival queens. He again with a greater oath declared that he knew better, for he saw that queen *'sting that drone stone dead,'* and was unable to extract her sting without tearing out her own entrails. Still, he said, the queen lived, and he released her into a swarm with her intestines still protruding.

"From this circumstance the reader can easily divine my convictions, that it was a case of fertilization beyond all doubt, as it is a known fact that the drone dies suddenly in the act of copulation, the genital organs adhering to the queen. As my friend was entirely ignorant of the natural history and instincts of the bee, he had confounded these widely different acts. I simply give this to do justice to my friend Atherton, for had it not been for this remarkable circumstance I should probably never have thought of investigating the subject.

"I now give the exact course I pursued. Having found, about one o'clock in the afternoon, a young queen of extraordinary beauty before one of my hives which had reared a young queen, and this was about the eighth day after hatching, I lifted her up and found her wings deficient. I well knew that she never could fly, and took her as a subject for experiment. Knowing that she left the hive on her wedding excursion, and had fallen to the ground when attempting to soar aloft into the air in pursuit of the drones, and believing that this was the proper time to secure success, I at once caught four or five extra drones, and entering the house took a wine glass and placed it in a window where the sun shone brightly, and put the queen and drones therein. The drones flew in the glass to escape, and the queen tried to fly, but could only hop and flutter. She noticed the drones, but they paid no attention to her, and in a short time they quieted down and stood still on the bottom by her side. I then became discouraged and gave up all hope of success, and to make it worse, my mother laughed at and made fun of me. I left the room chagrined and vexed to think that I had thus failed and become a laughing stock: but my sorrow was of short duration, as my mother informed me that the queen had just killed one of the drones. I at once became excited and ran into the house, and to my joy and surprise found a drone "stone dead," and evident signs of fertilization visible on the abdomen of the queen. I removed her at once to a nucleus box, introduced her, and in three days she laid eggs and has done well. I sold her for ten dollars. I tried two others, four days old, the next day, but failed entirely. Those were perfect queens, and could fly. I tried them on the fifth and sixth days after hatching, but did not succeed. I then left them to fly according to their instincts, to meet the drones in the air. This they both did on the eighth day. By this you see I was successful with two queens, and failed with two. Not being discouraged, I resolved to change the programme, for I discovered that the drones and queens wearied themselves, and soon became exhausted. To remedy this evil I cut a large hole in one of my honey boards, so as to admit a large lamp chimney. I then placed wire cloth on top of the frames some six or eight inches square, and set the lamp chimney level on the wire cloth, inserting the glass chimney through the hole cut in the honey board. I then watched for some of my young queens to make their appearance, and as soon as I discovered one I caught her and ten or twelve drones, dropped them into the top of the chimney, and corked it with paper, and the first trial the queen mated in less than one hour with one of the drones. I removed her and cut off one of her wings so that I could not be deceived. The next trial I failed entirely, for reasons I cannot assign. I have tried the tumbler and glass chimney very often since, and succeeded about half of the time. I succeeded in one instance where a queen had hatched without wings, having small knots where the wings should have been. This I accomplished with the tumbler, as first related. This queen was clumsy, and did not become very prolific, and I lost her in introducing her to strange bees, but reared some extra queens from her brood. I have tried Mrs. Tupper's process, as she described it to me, and was successful to a reasonable extent.

"One point more and I have done, for this time, and that is, that I have seen young queens that had mated three or four times with different drones, but notwithstanding I am satisfied that such queens have really been impregnated only with the last drone. My reasons for believing so are founded on facts obtained by close observation. First, I never saw a queen yet that mated with more than one drone in the tumbler, the glass chimney, or by the process described by Mrs. Tupper. I think I have discovered the cause why young queens fail to become fertile. After meeting the drones they always return to the hive with the genital organs adhering to them, and if caught immediately and confined over night, they almost invariably prove to be fertile. I caged over forty queens this summer, for this purpose, and not one of them left the hive the second time in search of the drones. Of this I am sure, for I clipped their wings. By caging the queens as soon as they return, you prevent the workers from detaching the organs of generation adhering to them. I have found that to remove this immediately will usually prevent impregnation. I have removed it from some queens three or four times this season; and thus prevented impregnation. Every observing apiarian, if this subject ever attracted his attention, knows that the workers will remove this foreign substance from their queen, and it is common in a short time to see one of them coming out with it. This untimely removal, in my weak judgment, is the true cause of such queens mating with different drones—my experiments, at least, go far to establish this fact; and if my experiments prove this point, the theory that queens are often *fertilized* with several drones is erroneous, and this cannot be the reason why the progeny of a *pure Italian* queen contains some *workers* purely Italian, whilst others are as purely the common black bee."

The difference between Mrs. Tupper's method and the one described above is very slight—only a difference in the manipulation—the principle being the same. Mrs. Tupper confined the queen, five days after she issued from the cell, in a wire cage with the selected drones. The cage was then laid on the frames of the hive, and covered over and left there for 36, and in some cases 48 hours. The cage was about six inches square by eight inches long. Mrs. Tupper claims that in such a cage the queens were fertilized, though she admits that last year she had several failures. I also learn through private correspondence that J. E. Ponet tried a similar process last year, and believe he succeeded in getting several queens fertilized by selected drones. Rev. Mr. Truesdell, of Warwick, P. Q., was also experimenting last year, testing the process given by Mrs. Tupper. How he succeeded I have not yet learned. I hope he will give the results of his experiments in your journal for the benefit of your readers.

I fully intended to test the process last year, and did make one trial, in which I failed, but was prevented from giving it any further attention. I still have my doubts whether any queens have ever been fertilized in confinement. It is so contrary to their nature and habits that I should feel half inclined to doubt my own eyes if I saw it.

It has been already stated, and is a well known fact, that it is the natural habit of the queens to mate with the drones on the wing, and in no other way, if left to themselves. I am therefore inclined to receive with caution any statements that they have been fertilized in confinement. I have long thought that some process would be discovered whereby impregnation would be in a measure under the control of the apiarian, but cannot readily believe in a process so at variance with their natural habits. In corresponding with J. E. Pond, of Roxboro, Massachusetts, who fully believed that he had succeeded in getting several queens fertilized artificially in confinement, he admitted that he was, to use his own words, "dead sure in only one case." Mr. Freeman Moore, in giving the results of his experiments which appeared in my last, states some things which are a little hazy, and cast a shadow of doubt over all. He does not believe the statement made by his friend Henry Atherton, that the queen stung the drone to death, but thinks that Mr. Atherton saw the queen impregnated by the drone, for he says a queen will not use her sting except on a rival queen. In this he is mistaken, for a queen will sometimes, when confined in a tumbler, sting to death a worker bee if introduced into the tumbler with her. Hence there is no reason to doubt that, in some cases, she would sting a drone to death if introduced to her, and it is altogether probable that Mr. Atherton was quite correct in saying that the drone was stung to death. I believe, however, it is not generally known that a queen will sometimes, when confined, sting other bees, as well as rival queens. Again, he says, "my mother informed me that the queen had just killed one of the drones, and to my joy and surprise I found a drone 'stone dead,' and evident signs of fertilization visible on the abdomen of the queen." Now, the drone does not die instantly after coition; therefore in that he was mistaken, and he may have been mistaken in thinking that the queen was fertilized. True, he says he removed her to a nucleus box, and in three days she laid eggs and did well. But she may have left the nucleus box on the first day after introduction, and mated with a drone on the wing. Indeed, it seems more reasonable to suppose that she did so, as a queen generally lays in 48 hours after impregnation, and 48 hours after the first day she commenced to lay, which would make it just three days after he introduced her into the nucleus box, at which time he said she commenced to lay. I fear the experiments have not been carefully conducted, and that after all it may turn out that the queens were fertilized in the usual manner. On the other hand, one can hardly believe that Mrs. Tupper and others have been mistaken in every instance. Doubtless, it will, this season, be settled beyond dispute.

I have already stated that, when coition takes place, the organ of the drone is left attached to the body of the queen. If, then, a queen is confined with drones, and during this confinement the organ of the drone is found attached to the body of the queen, the question is settled. Those who may desire to experiment will remember that the queen goes out to meet the drones from five to eight days after issuing from the cell, and the proper time to confine her with the drones will be during that time. It will also be absolutely necessary to keep the queen confined in the hive until the proper time, lest she go out earlier than usual. I would advise keeping her in the hive until the eighth day, and then introduce her to the drones.

FURTHER EVIDENCE OF THE SUCCESS OF MRS. TUPPER'S PROCESS.

Since writing the foregoing article, I have received additional evidence of the success of Mrs. Tupper's method. Some time in early spring, last year, A. Malone, Esq., of Garden Island, wrote to me to know if I had yet published Mrs. Tupper's process, as he had not seen it. I wrote to him, describing the process, but not knowing how he had succeeded with it, I made enquiries of him by letter a short time since, and I subjoin his reply. It is quite satisfactory. I hope Mr. Malone will give us notes of his success the coming season. I do not think it at all necessary to remove the queen from the stock on which the cages containing the drones and queen to be fertilized is placed. By removing the honey board, three cages could be placed on the top of one of my hives at the same time. Let others try it and report.

J. H. T.

"J. H. Thomas, Esq, Brooklin, Ont

"Dear Sir,—Your favour of the 14th inst., asking for information relative to the fertilization of queens by Mrs. Tupper's process, is before me, and in reply I would beg to say that I had queens fertilized in that way several times last season. I commenced early in the spring to try and raise a number of colonies from one, as described by Mr. Tallup. (I think in the January number of the *Bee Journal*, for 1868), and having lost every queen I raised by letting them fly out for fertilization, I at last tried Mrs. Tupper's plan, and succeeded. I first made some small Nuclei hives, and inserted three frames in each (with brood and comb in them), and placed a queen cell in each in such a manner that by turning a button I could see the cell. As soon as the queen was hatched I caught her and placed her in a cage made six inches square by eight inches long, two sides of the cage being wood, the rest wire, and placed a good number of worker bees in with her, and put the cage on top of the frames in one of your hives containing a good swarm of bees, having first removed their queen. When the queen was five days old, that is, on the fifth day, I took out all the worker bees, and placed seven nice large *drones* in with the queen. I have a door in one of the wooden sides of my cages, which makes it handy to put in, and also to catch the queens. I left the queen and drones together forty-eight hours in the cage, having placed them back again on top of the frames, and replaced the cover and plugged up the ventilators which are in the sides of the cover, to keep out the light. Of course I put some honey in the cage, out of the reach of the bees below in the hive, to keep the queen and drones from starving. Each time on examination, I found (with one exception) a dead drone, having all the end of his abdomen burst open, and twice I noticed evidences of copulation on the queens. To make myself doubly sure that they were fertilized by this method, I introduced the queens into new swarms, and closed the slide, so that nothing but a worker bee could go in and out, and all the queens, (with one exception, as mentioned above) in a few days commenced laying, and reared nicely marked Italian workers. The reason those that flew out for fertilization were lost is, I think, that on account of my living on an island, and having very few drones, the queens attempted to cross the river and were lost.

"Yours, etc.

"A. MALONE."

Household.

Dry Cellars and Door yards.

In building a house, few people think as they ought of the future, or that in all probability their lives will be spent in it. A farmer, when commencing to build a farmhouse, usually begins by putting some temporary kind of foundation under it; oftentimes only of block, the refuse of the framing timber used.

If a cellar is dug, it is often a mere hole in the centre, with the earth thrown out on one side, there to remain an unsightly heap or heaps, as the case may be, until nature covers the abomination with grass or weeds, thereby hiding somewhat its untidy appearance.

Moreover, houses are almost all built in dry weather, and often a level place is from necessity selected as the site. When wet weather comes on in the fall, there is no possibility of moving out of doors for the mother and children, without splashing through the mud that always accumulates around any frequented building. Dirt, filth, and wretched appearances are the result, instead of a clean, comfortable dwelling. Every man who enters the dwelling brings in bootloads o mnd and mire to be distributed through the house; and no wife's temper can be expected to bear this unnecessary annoyance. Recollect, too, this misery usually lasts a lifetime. The remedy after the house is built is very difficult; but is easily provided if thought of at the outset. I have seen hundreds of such muddy door-yards; in fact, to find one ordinary farmer's house *without* such a muddy mess all aronnd it in wet weather, is the exception, and not, as it ought to be, the rule. Now, all this is most readily avoided by a small outlay of labour and foresight at first as will be seen by following the accompanying suggestions. I will venture to say the outlay will be amply repaid the first and second year in the increased profit of a dry comfortable door-yard, and raised terrace or platform round the house, and an excellent frost-proof cellar under it.

Let us now commence to lay out our foundation, and suppose we are going to build a frame house of about thirty by twenty, or any other size that may suit the means of the builder.

I would by all means advise those who can afford it to build large enough at first, and those to whom it would be too expensive to do so, ought to calculate so to arrange the small house they build, that in future they can add a portion to it, as their family increases, or means to build more extensively are gained. To this class of builders, who must in the ontset limit their accommodation, I would urge that it is always better to so arrange the house, that the passage way passes along one (say the west) side of the house, thus building the present house on one side of it; so that in future any additions can be readily put to the west side of it, without interfering with the architectural appearance of the building, leaving of course the necessary projections to attach the addition to at some future period. This foresight also allows of the first house so made to answer as a kitchen and offices, and the new addition, when completed, to be used as a parlour, and a better and more convenient class of rooms.

As I before said, we will now proceed to stake out our foundation, say as above, twenty by thirty, and as an absolute necessity also to dig a cellar *under the whole house*. The excavation may be deeper or otherwise according to circumstances of drainage; but we will suppose, as is most commonly the case, that the house must be built on a comparatively level place, with only about four feet drainage fall at the lowest. The surface earth that comes out first must all be put away towards the front, but distributed in small heaps, and at such a distance only as will enable it hereafter to be thrown back to enrich the surface of the front.

The excavation of a cellar of four feet deep will, of course, cover an area around the house four times as great if spread over it one foot deep. A terrace would then be formed, raised one foot all round the house, and extending nearly twenty feet in all directions. Now, having thrown back to the front or sides of the raised part all the surface earth, it can afterwards be spread evenly on that portion to be used as a flower garden, or better still, as a lawn. On this raised portion, Mamma or the children can at all times and seasons move about in cleanliness and comfort; and, moreover, it forms a most ornamental addition to the house, as the edges must be all trimmed straight, and laid at an angle of about thirty degrees, and sodded over so as to prevent foundering. It is not a long or troublesome job to sod over the whole plat or terrace; about two days' work of two men and a team will cut and haul all the sod requisite, provided a plough of the wide share construction is used to cut the turf, and about two days more will lay it down, and finish it completely. The turf must not be cut thicker than two inches, or it will be troublesome and heavy to haul. Before the sods are laid, the land must be all perfectly level and smooth, and the turf when complete must be patted, or rolled level and smooth. An ordinary pavior's rammer is an excellent thing to level turf with, and can be made in half an hour.

Our cellar being now dug, and terrace made, we next proceed to form our cellar walls. The best course for a farmer to adopt is to erect round cedar posts, of say about seven or eight inches in diameter, and nicely barked, or carefully squared up, the lower end sunk about one foot into the cellar floor, and the upper end morticed into the sill above, which rests on these posts, which should not be more than six feet apart Stretchers, four by four, must be let into the posts at the back; one at the bottom, about six inches up; one at about two and a half feet, and one at about five feet from the ground. Less in number than these will not support the earth, without danger of bulging in, and thus looking unsightly. At the top a fillet or batten is nailed to the under side of the sill, about two inches from its face. Now you must take two ply of inch boards (rough edge cedar is infinitely the best) and stand up all around, the outer ply breaking joint with the inner. They must be squarely and carefully cut off at the top to fit tightly against the fillet or batten, and yet to fit up close under the sill. Square edged cedar is difficult to be obtained; but rough edged can be had anywhere that sound logs can be got to a saw mill. It is much cheaper and better, as well as more durable, than any other lining that can be used: pine will decay directly. After all the boards are carefully put in their places, the earth is to be filled in, and the water table fastened against the sill. To protect the sill from decay the water table should be nailed to inch stripe fixed upright on the sill at every two feet all round the building. This space between the sill and water table will defend, for many years, the sill from decay. Immediately under this, another cedar board is to be nailed on, still leaving the space; this board will allow of the earth lying close against it, but yet leave one inch behind and between it and the sill, to prevent decay; and this arrangement also admits of renewal in after years without disarranging the main portions of the cellar lining. The careful foresight thus so cheaply used will cause the wooden foundations of a house to remain sound for thirty years or more; and without it the sill would show signs of decay in five years. Of course all rain must be directed by spouts away from the foundations, if the cellar walls are to be kept dry and in good order.

A drain must be dug, if possible, but in some localities this cannot be done; and where all surface water is kept from running into the cellar, and there is no absolute spring, a very good substitute may be made by digging a well about four to six feet below the bottom of the cellar, but outside the house and close to it, with a communication from the bottom of the cellar floor by a drain. A pump in this well will, at all times, enable you to free the cellar from water in half an hour; and as this would not probably be required except in exceedingly wet weather the labour would be little.

It is quite clear a cellar must be had, and if the circumstances are not worse than described above, either remedy of drain or pump will be found to answer. We must have both cellar and earth to raise round the house, and this is far the cheapest way to obtain it. What is the extra expense entailed by doing this? The contents of the cellar will be about ninety or one hundred cubic yards, and can generally be excavated for ten or twelve cents a yard. To do otherwise than here described, on the score of saving of expense, is very poor economy. With such a good cellar the butter of ten cows will, from its better quality alone, pay all the expenses in two seasons, if not in one. Consider what an advantage it is to have such an excellent cellar, with everything cool and sweet in the summer, and free from frost in winter. Any root cellar, for house purposes alone, ought to be built just the same, but detached from the house, under some shed or other building to keep off the rain; it can be made to communicate with the cellar by a door. The roots, potatoes or turnips can be got into the root house through a trap in the upper part, and thence into the cellar for use by the door of communication. A small ice-house about six feet square, also with a door of communication with the cellar, would be an exquisite luxury, and cost hardly anything to build. Full particulars for building such an ice-house, as it exists attached to my cellar, will be given in some future number. C.

Earth Closets.

The only positive requisite is the dry earth or dust. A supply is easily shoveled up from the roads in August or September, but if none was secured, and if artificial drying is inconvenient, of if none can be scraped up from sheds, the siftings of coal ashes answer very well, better as a friable divisor than the earth, facilitating the intermixture of the manure with the soil to which it is applied, but perhaps not quite so effectual in retaining all its good qualities. But these will not escape if the ashes are used in sufficient abundance to absorb all the liquid without becoming saturated with it. A common tinful of this very dry ashes or dust poured after every use of the seat, will effectually prevent everything offensive to either sight or smell. It is best received on the ground, as if any wooden receptacle is used it will absorb some of the liquids, and as the dust cannot follow them into the wood, the latter will soon become offensive. And it is more convenient to shovel the harmless compost off the surface of the soil than to lift it out in a wooden box. I have seen plans of self-working seats much simpler than those of Mr. Moule, but it seems scarcely worth while to take the space necessary to describe them, when an old tin cup answers perfectly and conveniently.—*Country Gentleman.*

A Working Dress for Farmers' Wives and Daughters.

To the Editor.

SIR,—I trust my fair friends will pardon me if I draw attention through your journal to a matter of domestic interest, which I think deserves more notice than is usually accorded it—namely, the every-day dress of our farmers' wives and daughters. Many of our farmers' daughters are trying to follow city fashions regarding dress, to an extent beyond what is advisable for their own good, or the comfort of others. How often does it occur when they (the girls) are called upon during the forenoon, or while engaged in house work during the after part of the day, that visitors are kept waiting for an unpardonable length of time in some gloomy-looking room into which they have been ushered, though the callers may only have some trifling business which would take but a few minutes to attend to; yet the parties must wait, no matter what haste they may be in. When the girls do come, they are dressed to perfection, and certainly it would be *cruel* then for the callers to leave immediately after they did their little errand, considering the time and trouble which it has taken to make the girls "fit to be seen."

Now, Sir, do you not think so much dressing is needless for farmers' daughters just for receiving callers. To be sure, many girls are *not* "fit to be seen" in the dress in which they do their house work; it is so dirty and ragged, and worn so slovenly, that it is no wonder that they are ashamed if thus caught. But might not a dress be devised which would be both neat in appearance and convenient for working, in which the girls could perform their household duties and receive callers during the forenoon. Perhaps the girls are ashamed of being caught at work, hence do not like to be seen in their working dress; but they have no more reason to be ashamed of work or their dress than farmers' sons; and the boys hardly ever run and hide in the stable or barns when a lady appears in sight, but generally are glad to meet them, though it be in their working dress. The mechanic does not feel ashamed if met in his working clothes by a young lady; nor does the plough-boy apologise for his dress if caught by half a dozen ladies. I like to see the ladies dressed neatly; but why dress in such extremes, sometimes in dirt and rags, then in silks and satins? Again, so much precious time is lost both to the callers and the called, while very often it is a great inconvenience to both parties, but more especially to the callers. I hope the hint will be taken, as it is meant, in good part, and trust that some abler correspondent, perhaps of the other sex, will take up the subject.

York. CULTIVATEUR.

A young Portland woman, recently married received from a gentleman friend a large corn broom as a wedding present, accompanying which was the following piece of poetry:

"This trifling gift accept from me;
Its use I'd recommend,
In sunshine use the brushy part,
In storms the other end."

A very fine dressing for the hair may be made by mixing good pure glycerine with rosewater, one part of the former to three of the latter. Another has been found to make the hair soft and moist, and to retain these properties for some time. This consists of the white of eggs mixed with equal parts of alcohol, or used without the alcohol. After applying it the hair should be thoroughly washed with warm water.

PROTECTION OF WOOD FROM FIRE.—Woodwork is protected from fire by being painted with a mixture consisting of 5 parts of alum, 7 parts of rye-meal paste, and 30 parts of previously washed, finely divided clay. This mixture is used for woodwork not exposed to the open air. For woodwork so exposed, a mixture is used consisting of 2½ parts of crystallized sal ammoniac, 1 part of white vitriol (commercial sulphate of zinc), 2 parts of joiners' glue, 20 parts of zinc white, and 30 parts of water. These mixtures have been found to prevent wood bursting into flame on ignition, and to greatly delay its destruction even when severe fires are raging.

Poetry.

WHICH?

"Which shall it be; which shall it be?"
I looked at John—John looked at me
(Dear patient John who loves me yet,
As well as though my locks were jet,)
And when I found that I must speak,
My voice seemed strangely low and weak;
"Tell me again what Robert said!"
And then I listening bent my head.
"This is his letter:

"I will give
A house and land while you shall live,
If, in return, from out your seven,
One child to me for aye is given."
I looked at John's old garments worn,
I thought of all that John had borne,
Of poverty, and work and care,
Which I, though willing, could not share;
I thought of seven mouths to feed,
Of seven little children's need.
And then of this.

"Come, John," said I.
"We'll choose among them as they lie
Asleep:" so walking hand in hand,
Dear John and I surveyed our band.
First to the cradle lightly stepped,
Where Lillian, the baby, slept.
A glory 'gainst the pillow white;
Softly the father stooped to lay
His rough hand down in a loving way,
When dream or whisper made her stir,
And huskily he said, "Not her—not her."
We stooped beside the trundle bed,
And one long ray of lamplight shed
Athwart the boyish faces there,
In sleep so pitiful and fair!
I saw on Jamie's rough, red cheek
A tear undried. Ere John could speak,
"He's but a baby yet," said I,
And kissed him as we hurried by.
Pale, patient Robbie's angel face,
Still in his sleep, bore suffering's trace;
"No, for a thousand crowns, not him,"
He whispered, while our eyes were dim.
Poor Dick! bad Dick! our wayward son,
Turbulent, restless, idle one—
Could he be spared? "Nay, he who gave,
Bid us befriend him to the grave:
Only a mother's heart can be
Patient enough for such as he.
And so," said John, "I would not dare
To send him from her bedside prayer."
Then stole we softly up above,
And knelt by Mary, child of love.
"Perhaps for her 'twould better be,"
I said to John. Quite silently
He lifted up a curl that lay
Across her cheek in wilful way,
And shook his head. "Nay, love, not thee."
The while my heart beat audibly.
Only one more, our eldest lad,
Trusty and truthful, good and glad—
So like his father. "No, John, no—
I cannot, will not, let him go."
And so we wrote in courteous way,
We could not drive one child away;
And afterward toil lighter seemed,
Thinking of that of which we dreamed,
Happy in that not one dear face
We missed from its accustomed place;
Thankful to work for all the seven,
Trusting the rest to One in Heaven!

Agricultural Intelligence.

Double-furrow Plough Competition.

The following account, taken from the Edinburgh *Scotsman*, of a trial of double-furrow ploughs near Dalkeith, Scotland, will be interesting to our readers from the fact of the implement being regarded as originally a Canadian invention :—

A double-furrow plough competition, under the auspices of the Dalkeith Agricultural Society, took place recently on the farm of Wester Cowden, near Dalkeith. Double furrow plough trials have become so common of late that agriculturists are apt to forget that such implements were introduced to their notice many years ago. Apart altogether from the original Somerville plough of this description, a double and triple furrow agricultural implement of a form allied to that now in use, was brought under the attention of farmers in the United Kingdom in 1862 by Mr. Sovereign, who came over from Canada for the purpose of introducing it, but on account of want of patronage was compelled, after expending both time and money, to retire to his native wilds in the Far West. Since then, local inventors have been endeavouring to improve on the Canadian invention. Within the past few years agriculturists in Scotland have recognized the immense value of the double-furrow plough, and among the many inventions which are considered improvements on the original implement, considerable doubt has existed as to which would prove the best over all the different qualities of land. With this view competitions have been held all over the country, and it may reasonably be held that that which has taken the majority of prizes maintains the precedence over the others. It has been said that a plough may make better work on stiff land, and yet be far behind others on light, easily-wrought ground, or *vice versa;* but the implement which can secure the approbation of agriculturists on both varieties of land may well be looked upon as the champion plough. In order to decide this point, the Dalkeith Agricultural Society recently offered prizes for the best double-furrow plough, and the result was an interesting competition. Ont of the seventeen ploughs which were entered, thirteen came forward to try conclusions. The ploughs were first tried on a lea field composed of stiff clay, and after ploughing their allotted space they were taken to stubble ground which had been manured, on which the capabilities of the different ploughs were fully tested.

The following are the results of the trials as tested by the dynamometer, under the hands of Mr. Slight, practical engineer to the Highland and Agricultural Society : Messrs. Gray & Co.'s, Uddingstone, G. B., 6 cwt.; second trial, 5 cwt. This trial was particularly interesting, inasmuch as Gray's plough was tested by the dynamometer with high-crested irons, which drew 6 cwt. At the request of the judges, the plough was tried with plain or obtuse cutting irons, and the draught of the plough with these irons was only 5 cwt., or exactly the same draught as that exhibited by a single-furrow plough made by Ponton, which was tried over the same land, drawn by two horses.

LEA—1st, Messrs. J. Gray & Co.'s, 5 cwt.; 2nd, Wm. Shivas', Aberdeen, 7¼ ; 3rd, Mr. Mitchell, D.F.C., Peterhead, 7. Commended, Mr. Pirie's, Keith, 6½ ; Mr. Murray, H.G.L.M., Banff, 7 ; Mr. Murray, H.D.M.R., 8¼ ; Mr Mitchell, D.F.F., 7 ; Mr. Guthrie, Montrose, 6¾ ; J. Gray & Co., G.A , 7½ ; Mr. Anderson, Monifieth, 8¼ to 9 ; Wm. Kirkwood, Lothian Bridge, 9 ; Mr. Guthrie, 6¾.

STUBBLE—J. Gray & Co., G.B., 6¼ cwt.; Mr. Murray, Banff, 7.

It will be seen from the above that Messrs. Gray received the first prize of £5, and on the lea their plough was, with the square bottom, of as light draught as that shown by one of Ponton's swing ploughs, namely, 5 cwt. Only two ploughs were tried on the stubble, Gray's and Murray's, and the former had the advantage of half a hundred weight ; but on account of the prize winner going half an inch or more deeper, the draught, according to the dynamometer, was 2½ cwt. more than the single plough.

Manufacture of Beet Sugar.

We learn by the *Berlin Telegraph* that on the 24th of February a meeting was held in the town of Norwich, County of Oxford, for the purpose of hearing the report of Mr. D. S. Butterfield, who had been delegated by a number of influential men from Oxford, to Fond du Lac, Wisconsin, to examine the Beet Root Sugar manufactory at that place.

The report Mr. Butterfield gave was explicit and interesting, including the exact *modus operandi* in the factory, a statement of its capacity, number of working hands, a minute description of machinery, and the amount of capital invested.

He had brought two samples of beet root sugar with him, the one a half refined white, the other a very bright crystal coffee sugar, both grades, in colour as well as in taste, equal to any manufactured from the cane juice. The proprietors of the factory at Fond du Lac (an American and two Germans, the latter experienced in this branch of industry), had invested $16,000, partly in the machinery, which they valued at $12,000 (exclusive of the steam engine, which, together with the building and premises, they had rented), and partly in procuring the beet, of which they raised about eighty acres themselves. It being the first year they manufactured, and not having worked up their full stock of beet root yet, they were not able to give him an accurate idea of the amount of profit made, but were confident that this would not fall short of $3,000, clear of all expenses. Mr Butterfield had taken some beet roots that were raised in the vicinity of Norwich to Fond du Lac, and in getting them tested by one of the experts in the factory, it was found that they contained an equal quantity of saccharine matter (namely, 7 per cent.) to those raised in Wisconsin.

Mr. Wm. Oelschlager, who had been invited to attend the meeting, was then called upon to give an address on this subject. His experience being derived from factories of the old country, which are all conducted on a larger scale than those in the United States, his remarks were confined to the former. He gave first a short description of the manner in which the beet seed is raised, then how the beet itself, adding to this some statistics showing the direct as well as indirect profits to the farmer in raising beet, in preference to the continual growing of cereal crops. He then described the interior and working of a large factory, illustrating this description by sketches of the different machinery. He concluded by giving some statistics showing how much money was sent annually out of Canada for sugar ; for instance, in the year 1860, $1,600,000, which might be kept in the country if factories of this kind were started here, and pointing out the benefit the country would derive, irrespective of this, by the increase of labouring hands required for these factories.

After a great many questions had been put to both the gentlemen, and satisfactorily answered, it was proposed, seconded, and without dissent resolved, that a company should be organized, with a capital of $12,000, with power to increase : and Messrs. Moore, Barr, and Butterfield nominated as a committee to get subscribers.

A vote of thanks having been tendered to Messrs. Oelschlager and Butterfield for the efficient report and instruction they had given, the meeting dissolved after nearly four hours' sitting, with the fullest confidence that they will succeed in raising the required capital in a short time.

The directors of the Sacramento Valley Beet Sugar Association have determined to enter largely this year into the cultivation of sugar beets, and the manufacture of sugar therefrom.

English papers are agitating anew the long-vexed question of the Game Laws, and it is stated that a decided effort is about to be made to call public attention to them, with a view to their total repeal. For this purpose a meeting was held in Birmingham on the 3rd of March, when the formation of a Game Law Repeal Association was set on foot.

The Northwestern Flax Association held its first annual meeting at Cleveland, Ohio, on January 26th. A memorial to Congress was prepared, stating that over five hundred thousand acres of flax are grown for the seed in the States of Ohio, Indiana, Illinois, Wisconsin, Iowa and Minnesota, and praying for the continuation of the present duty on gunny cloth.

Miscellaneous.

Pet Toads.

FOR THE YOUNG FOLKS.

I had four little girls all very fond of pets of any kind, rabbits, kittens, dogs, birds,—nothing came amiss to them to fondle and pet. One day, whilst moving some old currant trees, we unearthed four large toads ; fine fellows they were, with beautiful goldon eyes. Each little girl at once pounced on a toad, and claimed it for her own ; and forthwith they conveyed all four away to a snug house made out of a condemned soap box. A pet is nothing unless it will eat at almost any time. Every child knows this, and the great delight is to feed them to repletion, and the pet toads were not to be an exception to this general rule. When I came into the house from the garden in answer to the dinner bell, I found much apparent distress amongst the young folks because the toads would not eat. They had been tried with every green thing in the garden, but without success ; eat they would not, and I was at once appealed to for assistance. I told the little ones to allow their pets to remain quiet until about sundown, and then we should see "what we should see." I promised them a treat. I was called away, and returned about eight o'clock in the evening. In the meantime, however, my brother had come home, and explained the habits of the toads.

I was greeted with shouts of "come and see, come and see, Papa." All four with short sticks, and every child clamouring and screaming with delight. The cause was soon apparent ; each little girl darted away to an old pile of boards under the balcony, and shortly returned with a fine fat spider on the point of her stick. These spiders were regular fat, jolly fellows, and quite large. The stick, with spider on its end, was cautiously lowered to within about three or four inches of the toad's mouth. You might distinctly see the expression of its eyes—they were fixed for one moment on the spider, when, "Hey ! Presto !" the tongue flew out directly from the mouth, and attached itself with inconceivable quickness to the spider, and as quick as thought the spider was transferred to the toad's throat and swallowed. Numbers of spiders and flies were thus disposed of, and it was really wonderful to see with what unerring aim the tongue was shot out, and the spider swallowed. Many young readers may not know that the toad is thus provided by nature with the means of procuring a living, the tongue being of that peculiar construction that at the will of the animal it can be shot out several inches. I really think some of the larger toads would catch a spider nearly four inches from his mouth.

These toads were then fed from day to day, and became quite tame, hopping about anywhere, and following the children for some yards when being fed. They were such favourites that they must, of course, have a name each ; and as at that time the Grand Trunk Railway was just being built, the toads received the names of the four famous contractors, "Jackson," "Brassy," "Peto," and "Betts." As they were all just alike and of equal size, it became necessary or advisable to mark them ; and accordingly each toad had tied round its leg a piece of coloured worsted. Each had a different colour, so that each child could identify her own. These toads were thus treated for several months ; but as winter came on I saw the necessity of not interfering by domestication with their natural hybernating habits, and consequently removed them to a distant part of the garden, upwards of two hundred feet away. They were all wished "good bye ;" I am not sure they were not absolutely kissed ; I rather think that belonging to the youngest certainly was. Next morning they were all back again and in their house. They had climbed up, as they often had before, over the corner of the box, and all were snugly ensconced under the shelter provided for them. We removed them thus several nights following, each time farther away; and each morning they were back again and had climbed into their box. I then carried them still further, into a piece of wood at least four hundred feet away, and next morning all were missing but "Jackson." He had returned and was again in his box ; but the rest never came back ; and "Jackson," when carried away once more, gave up the idea, and remained where put, at the foot of an old beech tree, with splendid accomodation to be found amongst the roots for a winter habitation.

I had brought up my children to see the folly of the usual conduct of young ladies, in showing disgust, and even screaming, at the sight of any animal or insect. I recollect that one of my children (all girls at that time) was dreadfully afraid of rats; her's was genuine horror at even the sound of them. I caught one in an iron cage, and made a pet of it, and for weeks we used to feed it, to familiarize the child with the sight and sound of it. This had the desired effect, so far as the child was concerned ; but the rat never made such a nice pet as the toad ; it always squeaked lustily when approached too rapidly, and even to the last it never was quite fearless. We let it go free when the end of its captivity was answered, and what ultimately became of it I never knew. C.

CARE OF WAGGONS.—When you leave a waggon heavily loaded to stand a number of hours, put a support under the axletree. The strength of wood cannot be estimated by what it will support for a short time. It will bear up a third more weight for a few minutes than will be required to break it by continued pressure. Waggons are abused very generally, by overloading. If the axletrees do not break, they are sprung, and the wheels warped, which causes the vehicle to run hard, and shortens its existence.

It is said that many farmers in England intend to grow oats largely in place of wheat during the coming season, in consequence of the low price of the latter cereal.

VARNISH FOR COARSE WORK.—A cheap but good varnish for coarse work can be made in the following manner : Take of raw linseed oil 30 pounds, litharge 1 pound, and white vitriol half a pound ; boil them together until the water is all evaporated. This is very durable, and costs but little trouble to make.

WHETSTONES.—When first putting a new whetstone into use, try water upon it, and if this keep the surface from being glazed or burnished, oil will not be needed. Some stones work better with water than oil. A dry stone is very apt to give a wire edge. It has been said that a little carbolic acid added to water will increase the friction on either a whetstone or a grindstone.

MILLER'S TICK DESTROYER.

MILLER'S TICK DESTROYER.

MILLER'S TICK DESTROYER.

FARMERS are recommended to give this valuable preparation a fair trial. It operates promptly and effectually in destroying Ticks and other vermin pests, as we as in eradicating all affections of the skin to which Sheep are subject. No Sheep-owner should be without it. As a certain cure it has hitherto proved infallible. Other Dips may kill all vermin seemingly alive, but on examination after a short time, the Fleeces will be found to be as full of Vermin as ever. The Tick Destroyer penetrates to the Vermin in all grades of development, extinguishing both hatched and unhatched life.

N. B.—Parties residing in the County of Northumberland, will send their orders for hives to JOHN B. LAMB, Esq., Baltimore, Ont., as he has purchased the right for that County.—J. H. T. v.2-4-1t

MINISTER OF CANADA

V. [illegible] R.

EMIGRATION

TO THE

PROVINCE OF ONTARIO.

To Capitalists,
Tenant Farmers,
Agricultural Labourers,
Mechanics,

DAY LABOURERS,

and all Parties desirous of Improving their Circumstances by Emigrating to a New Country.

THE attention of intending Emigrants is invited to the great advantages presented by the Province of Ontario. Persons living on the interest of their money can easily get eight per cent. on first-class security.

Tenant Farmers with Limited Capital

Can buy an stock a Freehold [illegible] with the money needed to carry on a [illegible] farm in Britain. Good cleared land, with a dwelling and good barn and outhouses upon it, can be purchased in desirable localities at from £4 to £10 Stg. per acre. [illegible] farm hands can readily obtain work at good wages. Among the inducements offered to intending Emigrants by the Government, is

A FREE GRANT OF LAND

(WITHOUT ANY CHARGE WHATEVER.)

Every Head of a family can obtain, on condition of settlement, a FREE GRANT of two hundred acres of land for himself, and one hundred acres additional for each member of his family, male or female, over eighteen years of age.

All Persons over 18 years of age can obtain a FREE GRANT OF 100 ACRES.

The Free Grants are protected by a Homestead Exemption Act, and are [illegible]liable to seizure for any debt incurred before the issue of the patent, or for twenty years after its issue. They are within easy access of the front settlements, and are supplied with regular postal communication.

Registers of the Labour Market

And of Improved Farms for sale, are kept at the Immigration Agencies in the Province, and arrangements are made for directing emigrants to those points where employment can be most readily obtained. Several new lines of railway and other public works are in course of construction, or about being commenced, which will afford employment to an almost unlimited number of labourers.

Persons desiring fuller information concerning the Province of Ontario, are invited to apply personally, or by letter, to the Canadian Government Emigration Agents in Europe, viz: Wm. Dixon, 11 Adam Street, Adelphi, London, W. C.; J. G. Moylan, Dublin; Charles Foy, Belfast; David Shaw, Glasgow; and T. Simays, Continental Agent at Antwerp.

Also to the Emigration Agents in Canada, viz:

Markets.

[illegible]

[illegible] 57c.
[illegible] to 58c.
[illegible] 56c.
[illegible] to $8.
[illegible] to $ 50.
Timothy—$4 [illegible] to $6.
Tares—$1.75 to $2.
Flax—$2.25 to $2.50.
Hungarian Grass—75c. to $1.

HAY AND STRAW.

Hay in moderate supply, and selling at from $7 to $15
Straw—Fair supply, at $4 to $6.

PROVISIONS.

Dressed Hogs—$8.50 to $8.75.
Butter—18c. to 25c.
Eggs—16c. to 18c.
Potatoes—40c. to 50c.
Geese—75c. to $1.
Turkeys—$1.75 to $2.
Chickens—per pair, 75c. to 90c.

CATTLE MARKET.

The supply of cattle has been deficient, in consequence partly of the state of the roads. The following are the prices, dressed weight.

Beeves—From $6 to $8.75.
Sheep—From $3.50 to $8.
Lambs—From $2 to $5.
Calves—From $3 to $12.
Hides—From 5c. to 8c.
Calfskins—From 10c. to 12c.
Sheepskins—Green, from $1.18 to $1.50. Dry, from 80c. to 90c.
Wool—From 25c. to 28c.

New York.—*Flour*—Heavy; receipts 6,000 bbls.; sales 9,000 bbls at $4.50 to $4.90 for Superfine State and Western; $4 65 to $5 80 for common to choice Extra State; $4.60 to $5.45 for common to choice Extra Western. *Rye Flour*, Quiet, at $4.55 to $4.60. *Wheat*, Dull and nominally unchanged; receipts 18,000 bush.; sales 7,000 bush. *Rye*, quiet. *Corn*, Scarce; receipts 400 bush.; sales 16,000 bush. at $1.07 for old mixed Western. *Barley*, Quiet; receipts 500 bushels; sales 6,000 bush. prime Canada Western at $1.05. *Oats*, firmer; receipts 3,000 bush.; sales 21,000 bush. at 58½c. to 58½c. for Western in store. *Pork*, steady at $26.25 for new mess. *Lard*, firmer, at 14½c. to 14¾c. for steam, and 15½c. to 16¾c. for kettle rendered. *Butter*, quiet, at 14c. to 20c. for Ohio, and 20c. to 28c. for State. *Cheese*, firmer, at 18c. to 16c. for common to prime.

PROVINCIAL MARKETS.

Montreal.—*Flour*—Extra, $4.60; Fancy $4.40 to $4.45; Superfine No 1 Canada Wheat, $4.25 to $4.40; No. 2 Western, $3.80 to $3.85. Bag flour, 100 lbs., $1.80 to $2.10. *Wheat*, Canada fall, 97½c. to 98c.; spring 97½ to $1. *Oats*, per 32 lbs, 28c. to 30c. *Barley*, per 48 lbs., 45c. to 50c. *Butter*, dairy, 17c. to 18c.; store-packed, 14c. to 16c. *Ashes*, pots, $5.85 to $5.70; pearls, $7. *Pork*, Mess, $24.50 to $25. *Peas*, 75c. to 77½c.

Hamilton, April 5.—Flour, per cwt., $2.37 to $2 62½; bran, 60c. to 75c.; clover seed, $7 to $7.25; eggs, 20c. to 22c.; butter, 23c. to 24c.; apples, per bag, 75c. to $1; potatoes, per bag, 55c. to 60c.; dressed hogs, $8 [illegible] 50.

Ottawa, April 5.—Flour, extra, $5.25; No. 1, $4 [illegible] to $5; bags, mill, per 100 [illegible] $2.62½; do. [illegible] oatmeal, per 200 lbs., $4.50; rye [illegible] flour, 100 lbs., $1.75; butter, 20c. to [illegible]

The Field.

Hints on Autumn Work.

FALL PLOUGHING.—As much of this should be done as time and means will allow. Let the work begin as early as possible, in order that the teams may not be too much pushed to get it done before hard frosts render the work impossible. If every field intended for spring crops can be fall ploughed, so much the better. Land that is fall ploughed always is more certain to yield good crops, especially of barley and spring wheat, than if this work is neglected. Land intended for roots should never fail to be fall ploughed. There is more value and profit in the practice than most farmers ever dream of. On clay soils, especially, it is of the greatest value. If a barrel of salt per acre can be sown on such soils immediately after the fall ploughing is done, it will help greatly to dissolve and render available the mineral elements of plant food in them.

No harrowing should be allowed on fall ploughed lands. The rougher the state in which they can be left exposed to the action of frosts the better. It is generally noticeable that those farmers who give the most cultivation to their soils, provided they contain sufficient plant food, always obtain the best crops, and those who get their spring crops in earliest, and in the best manner, are least liable to suffer from such unfavourable seasons in early spring as that of 1870. Land that is fall ploughed, well laid up in ridges, and water-furrowed, is usually ready to be worked much earlier in spring than that not so treated.

SEEDING WINTER WHEAT.—Every effort should be made to get this operation performed as early as possible. A good tillering out in the fall is of great advantage to the wheat-grower, and with some varieties like the Soules and Blue-stem, it is especially so. The Diehl is allowed to be a variety that succeeds well only on good rich soils, and with good culture, though it may make a fair stand if sown somewhat late. The Lowe wheat promises well, though we are not yet well informed as to its particular merits. It is of fine quality where grown this year. The new varieties lately introduced by Mr. Arnold of Paris, and said to be obtained by cross-fertilization, we have not yet had an an opportunity of examining this season. Their value can only be determined by experience in successive years, and without this experience no one can rightly speak either in their favour or otherwise. Now that the once destructive wheat midge seems to have in a great measure ceased its ravages in the crops of winter wheat, our farmers can with confidence grow more of that old favourite, the Soules, than which probably there is no better and more suitable variety for this climate. It combines high quality with productiveness, under good culture, and always commands the top price in the market. Let particular pains be taken to have the seed wheat made clean and free foul from seeds.

SELECTING SEED CORN.—In those sections where corn can be profitably grown, it is well to be particular in selecting ears from the growing crop for next season's seed. The time to do it is just when the corn is ready to be cut. Choose the finest and largest ears from the strongest stalks, and particularly from stalks bearing two ears; the uppermost ear is usually the best. See that the corn completely covers the cob from bottom to top, and is solidly laid together. Open out the husks, but do not detach them, and hang up the corn by them in a dry place, there to remain all winter. By thus selecting the very best ears, the corn crop on a farm may be greatly improved from year to year in productiveness and value.

STACKING STRAW.—When the grain crops are being threshed out, let every care be taken to preserve the straw clean and sweet, by having it properly stacked, if there is not room enough to stow it away under cover. A vast amount of straw is uselessly wasted for want of a little attention to this matter, and frequently straw stacks are so badly put up, or get undermined by stock, that during the winter they get blown over, and smother some of the stock in the yard. We had a neighbour who lost several head of cattle in this way during a stormy winter's night.

TOP-DRESSING MEADOWS.—Those farmers who have on hand a supply of well rotted or composted manure should not fail to give a good top-dressing of it to such of their meadows as are most in need of a little stimulating in order to carry heavy crops of grass. The fall is the time to do this work, as then the manure will have the benefit of the fall rains to wash it down among the grass roots. It will also act as a slight mulch to protect the roots from being heaved out by frost. The dressing need not be heavy, say eight to ten waggon loads per acre, scattered evenly over the surface from the waggon box.

GATHERING APPLES.—In this matter there is often too much carelessness shown. Many find it less troublesome to sell the entire produce of their orchards, (reserving only such trees as may be required for a supply of fruit for home use), to some dealer, who having the facilities at command, and knowing the importance of care, will take pains to have them properly gathered, sorted and barrelled. In this case the farmer can generally obtain a fair price for good fruit, and runs no risk of loss from freezing up or bad handling. Sell as early as you can get a fair offer, and insist on a payment down sufficient to cover any risk of loss should the buyer neglect to gather them in time. The better the fruit, the better should be the price. Those who can spare the time and expense of barrels, and will take the trouble to gather and sort properly, and have a good place for storing away, will find their profit in keeping over their fruit, provided they have really valuable winter-keeping varieties.

POTATOES.—This crop should be taken up as soon as they are ripe, which is when the tops are dead. There is nothing gained by leaving them in the soil after they are ripe, and some risk run of freezing up, or rotting should the weather prove wet. On no account

SEP 7 1934 UNIVERSITY OF TORONTO

should they be stored away till they are dry, and yet they should not get exposed too much to the sun or their flavour will be injured.

GATHERING AND STORING ROOTS.—Do not neglect this operation too long, and get your crop caught in the hard jaws of Jack Frost while in the ground, as was the case last year with many. Sugar-beets must be taken up and stored before frost touches them; mangels and carrots are easily injured by frost, though they will bear a slight touch of it. Swedes can stand frost till it gets severe enough to harden the ground, but in any case they are safer if made sure of in good time, as soon as they have attained their growth, and they will not grow to any extent after the first hard frost comes. If they are taken up and piled in the field in small heaps, with a slight covering of straw or earth, to sweat a little before being stored away for the winter, they will keep all the better, and as soon as the ground freezes up advantage can be taken of fine days to cart them to the root-house or barn cellar.

FATTENING HOGS.—The earlier this is begun, after the food for them can be had, the better. If their food can be cooked, so much the better. Hogs thrive and fatten more quickly and at less cost on cooked than raw food. If that cannot be conveniently done, the next best thing is to have what grain or pulse is used soaked in water till soft and fermentation has begun. If, before putting up to fatten, every hog could be weighed, and its weight recorded, and an account kept of the weight and value of each kind of food supplied, and the state it was in when fed out, cooked or raw, and the hogs weighed alive before slaughtering, much could be done to ascertain which is the best and most profitable manner of fattening them. We hope some of our most enterprising readers will try some experiments of this kind with different foods and lots of hogs, and report results. It is well for the farmer to know by actual experience what he is about, instead of working in the dark, as too many do.

Let us have some careful and reliable facts about the difference between the live and dressed weight of hogs when slaughtered, noting the breed, so that something definite may be arrived at as to the value of each breed, and the amount of shrinkage that ought to be allowed in selling fat hogs alive. English experiments have shown that good, well fatted hogs will dress from 80 to 87½ per cent. of their live weight. It would be well to know which pays best, to sell the live hog or the dressed carcass.

CROPS IN NOVA SCOTIA.—The last number of the *Nova Scotian Journal of Agriculture* gives a favourable report of the condition of crops in that Province. Most of the cereals are said to be above an average. There is a great increase in the extent of wheat, oats, barley, roots, and especially potatoes, grown by the farmers this season. The pastures were in good condition and dairy produce was favourably reported.

Beet-root and Beet-root Sugar.

When we tell our agricultural readers that the value of the sugar and molasses which are imported into the Provinces of Ontario and Quebec yearly, (and the whole of which we could produce ourselves), amounts to nearly *Three millions of dollars*, while the wheat and flour which we export amount to only about double that value, the question seems too large to be dealt with by the agricultural community, and the farmer, with a sigh, thinks, "that is too big an affair for me; I must leave that to the Parliament of the Dominion." But when we tell the farmer there is a crop which he can raise on his own farm, which in value will amount (in addition to his other produce) to any sum from three hundred to one thousand dollars annually, he will begin to pay some attention to his advisers, and see if he cannot carry out what it is proposed he should do. This is the fact as regards beet-root sugar and the beet-root. It is a crop which every one can raise; and if once public attention can be directed to it, farmers will find it their interest to include this among their regular crops.

First, let us show what is done with beet-root and beet-root sugar in France, Germany, and Belgium; all of these countries no better adapted for growing the root than Canada is.

In the year 1866, the total sugar produced in the world from all sources was two millions three hundred and twenty thousand tons; and of this the sugar produced from the beet-root amounted to nearly one-fourth, and the whole of this beet sugar was grown in France, Belgium, Germany and the other European countries, none of which are more favourably situated for its production than Canada is. Of this enormous amount of sugar France alone produced two hundred and seventy-five thousand tons. In addition to this, an immense quantity of spirit was also distilled from the root direct, and from the molasses and other fermentable matters produced during the manufacture of the sugar, and most of which spirit is turned into French brandy. Now, if the French can grow sugar at this rate, the Canadians can also produce it when once the thing is understood, and its advantages appreciated.

Every farmer throughout Canada knows how to grow mangel-wurtzel, and consequently he knows how to grow beet, for the sugar-beet requires no other culture than the mangel; the man that can grow the one can grow the other. Undoubtedly, before we can have beet-root sugar, we must grow the sugar-beet, and it is fortunate that that root is not only as easily grown as the mangel, but is actually more profitable to grow as cattle food for the farmer. In mangels (or rather "mangolds," but the former term is now most generally used), the root consists of 91 per cent. water, and 9 of solid matter. In Silesian, or sugar beet, the root consists of 82 per cent. water and 18 of solid matter. Now, as the only profitable, nourishing part of the root is the solid matter, (for water can be supplied at a far cheaper rate than by growing it in the shape of roots), it is clear that it must be better to grow the sugar-beet than the mangel, for there is twice the solid matter in the beet; so that no one can have any excuse for growing the mangel in place of the sugar-beet. Again, to do well, the mangel must have a great deal of room; this allows for the growth of weeds, and requires at least one extra hoeing; whereas the sugar beet can be grown far closer together, both between and in the rows, and its leaves cover the ground and smother the weeds better than the mangel does. The sugar-beet grows more under the ground than the mangel, and when grown for sugar requires to be earthed up, and is doubtless somewhat harder to get out of the ground at harvest time; but being so covered, it is far less liable to injury from frost than the mangel, should accident prevent its being harvested, or should early frost set in.

Then, again, the mangel contains two per cent. of salt, while the sugar-beet contains only one per cent. of salt, so that the sugar-beet is the least exhausting crop of the two. There can, therefore, be no reason why the sugar-beet should not be grown on every farm, even if only used for cattle. It is more nourishing, less bulky, requires less house-room, is equally easily cultivated, and, in fact, more profitable than mangel; cows are fonder of it, it makes better milk and butter; the leaves are as good for food, and the crop is both a safer crop and a more profitable one. There is, therefore, no valid reason why the raw material for the sugar manufactories should not be produced here in any quantity.

We next come to the manufacture of the sugar, and here we find that popular prejudice has already implanted in the agricultural mind an idea that beet-root sugar can only be manufactured in large and expensive buildings, and on an enormous scale. This idea has got so firm a hold on the public mind, that it will take a good many small manufactories in actual operation to banish it; but that it will be banished is as certain as that sugar-beet can be grown as easily and with greater profit than mangel-wurtzel.

The manufacture of beet-root sugar was in the first place a state necessity. The great Napoleon's policy was that France should be self-sustaining, and should be independent of British and other Colonial produce; this could not be unless sugar could be produced as a French manufacture. Napoleon called in the aid of the great chemists of the day. They pointed out starch sugar and the sugar from beets as the only substitute. The starch sugar as an edible was soon abandoned, while that from beets was as quickly brought to a moderate perfection; the necessity of the state required an immense supply, and to

meet this, enormous manufactories were erected. These were fitted up, not by practical, but by scientific men; cost of production was in a measure lost sight of in the necessity for quantity, and the consequence was unnecessarily great expense in machinery and buildings, which, when erected, could not be altered or amended to meet the requirements of practice and experience and the progress of invention.

It is an indubitable fact that no manufacture ever reaches perfection so quickly as it does when it is originated by the people. Science comes in much better to mend practical errors than to originate processes. The object of science is to produce *in perfection*, that of popular effort is to produce with *profit*. Where a manufacture is in the hands of the people the utmost ingenuity of thousands is exerted, whereas, when science originates, it feels bound by its own rules, and seldom branches out. Science ignores accidents; everything must be produced and and carried as "secundem artem." Popular effort tries everything; and amongst the millions of experiments which popular effort makes, there will be many important successes which would never be attained by more regular means; accident has originated many of the most important improvements in the world. It is true that science can always step in and ascertain the reason of the success, and in doing so will almost always improve upon the original; but the purely scientific man, for his own credit's sake, will seldom go out of the beaten track, and incur loss or be supposed to commit errors, where there is but little or no probability of success. So it was with the cotton manufacture; when first started it was so profitable and promised such mines of wealth and easy work, that it called forth the exertions of the entire population; members of every imaginable trade left their ordinary avocations, and rushed to the spinning and weaving of cotton; the shoemaker, knowing the properties of leather, when he came to be a cotton spinner and weaver, introduced his original material into all such parts of his new machinery as admitted of it; the tinsmith and sheet-iron worker could, and did, prepare tools and machinery of equal efficiency, and at a quarter the cost of that made from more expensive materials; and so on with fifty trades, each one adapted such material and skill as he had originally used for a different purpose to the manufacture of cotton. Millions of mistakes were made, but hundreds of improvements were made also; the mistakes sunk with their projectors, the improvements, when aggregated, have made the cotton interest of England the greatest in the world. As it was said above, the opposite to this was the case with the beet-root sugar manufacture; it was required in full growth, and not having passed through the necessary stages of infancy, youth, adolescence, and maturity, came forth an imperfect, instead of a perfect, process.

Hence some of the most important elements of success are only just now being adopted. For instance, refiners of sugar had only been used to deal with sugar in its dry and crystallized state as brought from tropical climes, where skilled labour could not be had to refine it; hence, in the first manufacture of beet-root sugar, the coarse sugar was made from the juice of the root, and then subjected to the expensive process of refining to get rid of the impurities, many of which had occurred in bringing it to its crude state of brown sugar. Now, the case is altered; the refiner takes the juice when brought to a syrupy consistency, and before it is burned by evaporative process, (and it is always more or less so burned or coloured); the refiner now takes it in the state of syrup, whenever he can get it in that shape, and at once reduces it into refined or loaf sugar. Thus enormous savings are effected, and a more perfect production attained. The first beet-root sugar manufactory that has been erected in England is for syrup only; it belongs to a refiner, and as soon as the juice is sufficiently reduced he takes it off to his London premises and refines it into white sugar at once.

Another simple discovery has just been made. When, owing to certain accidents of manure or cultivation, the beet-roots have imbibed from the earth a more than due proportion of salt, they produce uncrystallizable sugar, to the great loss of both the manufacturer and the farmer. The extraction of this salt from the sugar was for a long time an impossibility, and such sugar as contained it and would not crystallize, was abandoned to the distiller or molasses cistern. Now, the following simple process is found to free the syrup from salt, and to render the sugar all crystallizable: Long troughs are provided with partitions at small spaces, which partitions are made of skin, bladder, parchment, or parchment paper; the compartments are filled alternately with syrup and with water. Thus, partition No. 1 will be filled with molasses or syrup; partition No. 2 with water, No. 3 with syrup, No. 4 with water, and so on. The article now used as being equally efficacious, and the cheapest, is paper, which, by the action of sulphuric acid, has been made into artificial parchment, and is called parchment paper. Improbable and impossible as it seems, the salt leaves the molasses or syrup and goes through the dividing partitions into the water, while the pure sugary syrup is kept back. When the operation is completed, which is in a very short time, the contents of the compartments are withdrawn, the sugar at once crystallized, and the salt liquid either reduced to its elements, or otherwise employed for different purposes.

Now, had the manufacture of beet-root sugar progressed naturally, from small things to great, these facts, and a hundred others, would have become known to the operators. Science, although it pointed out the evil, failed in the first place to produce the remedy, although when produced, either by experiment or accident, science has made the most of it, and added further improvements and information.

It will thus be seen that at the present time the manufacture of beet-root sugar is beginning to be so well understood, that we can afford to drop the heavy and cumbrous machinery adapted to it in large manufactories, and by simplifying the process adapt it to the means and skill of the producers of the roots.

NO. II.

It is only necessary to arouse the attention of the Canadian farmer in order to effect the manufacture of beet-root sugar as a home article, made as maple sugar is made, and by processes requiring far less skill than the manufacture of good butter and cheese. The farmer's common-sense reasoning is this: An acre of sugar beets costs no more to raise than an acre of mangels. When reduced into sugar by the help of the labour of his own family, and the wood growing on his own farm, he gets nearly two thousand pounds weight of sugar, while the refuse and other matters will fully pay for the expense of conversion.

Farmers will naturally say, "Yes, that may be all true, but I never saw beet-root sugar in my life, and I do not know that there is such a thing."

We reply:—"You never use refined sugar in your tea and coffee, nor use molasses or treacle that have been purchased at the stores, that one-third at least of each article is not made from beet-root sugar, grown on the continent of Europe, and brought into Canada under a heavy duty. You do not know this, but it is a fact.

Now let us look at the thing from a common-sense point of view, and there are thousands of readers who are quite as capable as the writer, or any other man, of analyzing and bringing down to everyday practice the elaborate system pursued in the large manufactories.

Sugar beets require to be ground or grated as finely as possible, but to that process we are all well accustomed in our cider mills. The juice then must be separated from the pulp—also in a similar way to cider-making. The more clear and perfectly strained the juice is, the more easy will be the subsequent process. If it is thought well, the sweet that remains in the ground pulp may be leached out with water, but whether it is worth doing so is a question for your own judgment. If you do not get the remainder of the sweet, the cattle do when consuming the pulp, so that it is possibly not worth the trouble of getting out more than you can squeeze out in your cider press. The juice will, of course, be strained into the boiler, and you then have what is equivalent to so much maple sap, only far sweeter and stronger, but there are impurities in it, and

these impurities must be got rid of. The first thing to do is to raise the heat of the liquor to 178 degrees Fahrenheit, then add quick lime which has been liquefied with water and strained, in the proportion of one and a half ounces of dry lime to one hundred pounds of juice. This is well mixed by stirring, and when well united, the heat in the boiler is gradually raised. The action of the lime combined with the juice causes a portion of the impurities to coagulate, while other portions seem to be caught up by the action of the lime; the whole of the impurities rise as a scum to the top of the liquor, and must be carefully skimmed off, taking care not again to mix them with the juice. In large factories they draw the purified liquor off by a tap in the lower part of the boiler, but in a private and small way, skimming will answer just as well. The liquor is not brought exactly to a boil, but the heat is raised and continued until the scum is properly formed. A little experience shows how to do this.

The purified juice is now boiled until it is reduced to a syrup-like state. In the boiling there will be a precipitate of some of the dissolved lime, which is not allowed again to mix with the juice.

This syrup is then run through a charcoal filter, which further purifies it, and it must then be submitted to the system of the troughs already described, containing divisions of thin skin or parchment paper. The action of these troughs takes out all the salts which the juice contains, and leaves the syrup with nothing in it but pure crystallizable sugar and water. The syrup is then further evaporated, until it is brought down to a proper strength for graining, just as maple syrup is, and it then is set by until the sugar forms; and this sugar can be brought to a greater state of purity by running off the molasses, and either refining it in the ordinary way or by claying it, which process will be described in a future article, or it can be run into cakes like maple sugar. Now there is nothing in all this which cannot be done by any person of ordinary intelligence. Any one who can make maple sugar can make beet-root sugar, if they will, by following out the course here pointed out, and the hints now given.

In cases where the farmer is near a sugar refinery, or within reach of one, the concentrated syrup is at once a merchantable commodity. All the farmer has in that case to do is to reduce the syrup to so strong a state that it will not ferment, barrel it up, and take it to the nearest sugar refinery, and they will gladly give all it is worth. This saves all the difficult part of the process, and gives the farmer a much better chance than he would otherwise have. There are now sugar refineries in Montreal on an enormous scale; there is one now erecting in Toronto which will also be very large, and in the course of far less time than it will take to persuade farmers to cultivate the roots, and prepare the crude syrup, that article will bring a definite price according to its strength and purity, and be merchantable at every country store, just as potash now is.

The first successful beet root sugar manufactory which has been established in England is at Lavenham. It has been established by a sugar refiner, and, as before stated, he only reduces the juice of the root to a syrup, which is then taken off in barrels to the refinery in London, and made up at once into refined loaf sugar, without first undergoing the process of making it into ordinary brown sugar.

Manufacturers prefer this, as they have less impurities to deal with, and sugar which has been injured by burning always contains a large proportion of a sugar that is uncrystallizable.

VECTIS.

Draining at Low Levels.

To the Editor.

SIR,—I am thinking of draining my land, but am rather puzzled about my outfall. The land slopes down to lakes in all directions, the low land at foot of the hills lying so near the level of the lakes that tile drains put in three feet six inches (and I don't think putting them shallower is of much service) would simply form a duct for the lake water to come into the land, instead of letting the subsoil water off; besides, I have always understood that letting the air through the outfall does as much good as letting the water out. Is not this so?

The only remedy I see is to bring my covered drains down until they are above high water level, then continue to the outlet in open drains; but this cuts up the field very much and prevents the use of mowing machines. Believing in machine work, I was thinking of getting one of Carter's Ditching Machines. My soil is loam on surface, with stiff clay subsoil, and tolerably strong. How would the machine work in such land, and at what distance apart do you consider drains should be put in such land?

Another question—Can soot be used to advantage on grass land; if so, when, how, and in what quantity?

IMPROVER.

Nova Scotia.

REPLY.—The only way to get over the difficulty is to lay a large sized tile drain along the bottom of the slope, giving it an inclination towards a point to be a common point for another drain coming from the opposite direction, and making an open drain down to the lake. This will certainly interfere to some extent with mowing machines, but if the leading drains are pretty long, two, or at the most three, open drains will do all that is required. The mouths of these tile drains being above the level of the water will allow the air to circulate, which has been found from the experience of late years to be a great help to drainage operations.

Carter's Ditching Machine, supplemented with some hand work to finish out the ditch to the requisite depth, works satisfactorily, as far as we know, and has been used without difficulty through such a subsoil as our correspondent's, though there is occasionally some trouble if there are many stones. They can, of course, cut a good many more rods in a day than a man, and have been found by the experiments to work cheaply.

Nine or ten yards would be a good distance to place the drains apart; the depth should be 3 feet 6 inches; and where practicable, the drains should come to the surface. Let care be taken, in joining the side and main drains, to have the side drains curved for ten to twelve feet in the direction of the fall—ordinary tiles are all that are necessary at the junction, and a few stones placed over the joints will allow thorough communication.

Soot makes a very efficacious top-dressing, applied in the Spring to grass lands.

Lifting and Storing Potatoes.

The potato crop of this season will not be a large one, not perhaps from lack of yield per acre, but because the low prices realized in the past season for this esculent have prevented many from cultivating it as largely as usual. Should the Colorado beetle extend its destructive ravages eastward of the point it has reached this year, we may find the potato crop so precarious as not to be worth growing except at a very high price. Last year we gave a cut of the best of the potato-lifters yet invented; and we have, so far, seen nothing of more recent origin.

In whatever way, however, the potato crop is to be lifted, it is well not to take out too much at a time. The exposure of the potatoes to the rays of the sun for any length of time is apt to give them a twinge of bitterness in their flavour. Let them be exposed no longer than is sufficient to dry them, and then have them gathered together in heaps and lightly covered with straw till they are to be hauled to the cellar or root-house.

When potatoes are to be stored away by pitting on the field, the greatest care must be taken to make the pits only on such spots as can be depended upon to retain no moisture at the bottom. If the land is clayey or naturally retentive of moisture, it is best to make a slightly elevated bed for the pit to rest on. If the soil is sandy and perfectly dry, such as is found on little knolls or hillocks, a small pit may be dug from one to three feet deep, and the potatoes dumped in, and piled up till they give enough slant to make a roof that will shed rain.

In covering the pits, it will be found that the potatoes will keep much sweeter and nicer, and be less liable to suffer from sudden and severe changes of weather, if they are covered with clean straw before earthing them up. Our plan was to have the grain in some sheaves beaten out with the flail, and the straw kept for the purpose of laying over the potato pits before covering in with earth. By doing this the straw can be laid like the thatch on a house, and be of more value as a protection from rain and frost than if it had been taken from the straw-stack.

It is well to have the potatoes sorted before putting in, if there is time to do so. Let all the small ones be picked out and put away separately, or carried to the barn to be fed out to the milch cows or store hogs.

If the potatoes are stored away in a cellar or root-house they must go into it perfectly dry, and should be divided into lots of about one hundred bushels each, with board partitions between to prevent the whole mass from getting heated and rotting. If they cannot be dried in the field before storing away, they should be drawn to the barn and spread out to dry on the floor. If there is any rot in the crop, the very greatest care must be taken to reject every potato that shows the least suspicion of it. It is better to do this than to find out, a few weeks afterwards, that one speck of rot had developed into such proportions as to necessitate the throwing away of many bushels.

Rye for Early Pasturage.

The shortness and inferior quality of the hay crop of this season make it probable that, by the time spring comes, many farmers will find themselves with less of it than is desirable to carry through their stock in good condition till grass comes. The price also may rule so high as to be an inducement to sell hay, rather than consume it on the farm.

In order to provide for this contingency, it will be well for those who breed stock largely, especially sheep, to grow some crop that will give them an extra early bite in spring, should the winter fodder not hold out.

For this purpose, nothing better adapted to the climate, or more certain to succeed than winter rye, can be found. It will grow on almost any soil, with very little preparation, and if sown early enough, will acquire such a growth before hard frosts stop it, that when the snow melts in spring the sheep will find a very good bite, and it will start again so early that much feed can be had from a field of it before there is a bite of grass in any of the meadows. The seed required will cost but little, as from a bushel to a bushel and a half per acre will be sufficient seeding. Stubbles, and land intended for fallows or roots next year, may as well be sown with this crop, if it is thought probable that there will be a deficiency of forage before grass comes again. But it is a very undesirable crop if allowed to go further and grow up to maturity, and those who sow it for the purpose of obtaining late fall or early spring feed must not be tempted by the fine appearance of the growth to neglect ploughing it up as soon as the stock can go to other pasturage. It is also better to be careful with stock when they are turned on such very early spring feed, and allow them to get gradually accustomed to it, otherwise the sudden change from dry fodder to green food will prove prejudicial by rendering them liable to scouring, and giving them a distaste to what dry fodder can still be spared to them. They should get out on the rye only for a short time each day, and in no case be allowed to live on it exclusively.

Thin Seeding of Wheat.

I notice a good deal of controversy in the English papers on this head, and being somewhat practical in my notions, and at the same time observant from habit, I am led to believe that all their theories and doubts, so far as Canada is concerned, will be swept away by the oft-repeated observation made in the spring by almost every farmer, namely, "My wheat is pretty good so far, but too thin." Who ever heard of wheat being too thick on the ground in spring in Canada? Very few; and what every one says must generally have a great deal of truth in it, at all events so far as the practical results go here. Wheat *may* do well at home if dibbled in at a distance of 12 x 9 inches; but I am very sure if our farmers had their crops winter killed so as to leave only one plant at this distance, they would make the above observation, and it would almost always be exactly the fault such a thinned out crop would have. "It would be too thin."

It may be that the land here, combined with our short season, will not allow of the stooling out of wheat so thinly sown; but such is the fact, and all the statements of English agricultural experience will not convince our farmers that they would be more certain of a crop, with plants at 9 x 12 inches apart, than if twice as thick. Such statements as those we read of in English papers are calculated to mislead, and sometimes to discourage experiment, unless followed out with great caution, and due consideration as to circumstances attending them.

C.

Storing Roots for Winter Use.

The most advantageous method is undoubtedly a cellar under a side-hill barn, where the roots can be cut up and fed out to the stock at one operation, and without the necessity of exposing them to severe cold in conveying them from the place where they are stored to the place where they are to be fed out. Except in a side-hill barn where the roots can be on the same floor with the stock, it is seldom advisable to have a root cellar under a building. If a cellar is made to hold them under an ordinary barn, it is apt to be damp, and the roots to suffer for want of ventilation. A root house, either on the surface or but little below it, and adjoining the cattle stables, is preferable to a cellar underneath them. The outside walls above the ground may be banked up with earth, and the top portion covered with stable manure. The root house may be made of two inch plank, if more substantial materials are not convenient. Where timber is abundant, a cheap and substantial frost-proof root house can be made of logs, the roof being made of strong poles, covered with pine branches, and then with manure or earth. The manure can be removed in spring, and a fresh coating put on each year. Where a root cellar is used for storing, it is well not to fill it too full at once, but to let a part of the roots be pitted on the field, and afterwards drawn in on mild days in winter or early spring, when the roots in the cellar have been nearly fed out. If very large quantities are stored in the root cellar, there should be partitions made to divide them into quantities of 200 to 300 bushels, to prevent heating.

Salt as a Manure.

With the present abundance of salt in Canada, it is most desirable that its value applied as a dressing to the soil should be definitely ascertained, which can only be done by means of actual experiment. It is not yet known as it should be, that salt, although not possessing chemical constituents of value as plant food, yet acts as a powerful solvent of those elements contained in the soil that, when dissolved, go to make up the bulk of the food of plants growing upon it. This accounts for the fact that the richer the soil the more likely is a dressing of salt to prove valuable to it. The best time to apply the salt would probably be, in the case of winter wheat, to sow it broadcast on the soil just before sowing the wheat; on land intended for spring crops it might be sown on the surface late in the fall on newly ploughed land, or very early in spring as soon as the land is ploughed for a spring crop. It is quite probable that the barley crop would be benefitted by the application of salt, as well as wheat. For mangels, salt is said to have been used in Britain with marked advantage. The quantity that can be given with profit can only be ascertained by repeated trials; but one barrel per acre is little enough to begin with. An increase of even one or two bushels per acre would amply repay the small cost of the salt, and it is likely that a much greater increase would be given in many cases.

It is said that in combination with lime, by slaking the lime with water in which salt has been largely dissolved, a good material for composting with swamp muck, and quickly decomposing it, may be obtained. The slaking of the lime with salt water causes

a portion of the muriatic acid in the salt to unite with the lime, thereby rendering it more soluble, while the soda left is then free to combine with any acids in the muck, and form soluble salts, thus making the composted material more quickly available as plant food for the crops to which it is applied. It is worth experimenting whether salt, if applied to barn-yard manure by throwing a little over the compost heap or yard once in a while, would make it more valuable and quickly available by the union promoted between the different materials in the manure heap.

Norway Spruce as Hedge Shelter.

Some weeks since I had occasion to visit the nursery gardens at Leslieville, and whilst there carefully examined the various hedges that are planted out, as proof of the efficiency of the various sorts.

The Buckthorn certainly makes a very handsome hedge, but it affords no shelter when most required in winter, and as a farm fence many years must elapse before it will afford protection against cattle; and one great fault all the Thorn tribe have, is that it is almost impossible to mend a gap in an old hedge, caused by accident or otherwise, by planting young quicks, as it is a well known fact that the old plants rob the young ones to such an extent as to seriously dwarf their growth, if not to kill them outright.

Hemlock hedges have a more serious objection; the plants are very difficult to be made to grow, and although the hedge when grown affords good shelter, yet it becomes hollow and bare at bottom in a few years.

Norway Spruce, on the contrary, grows freely, and, from some cause, old plants do not prevent young ones from growing when planted in their vicinity. The expense, however, of Spruce plants at present prices will, it is feared, prevent its general introduction as farm shelter; but for lawn and garden ornamental hedges, fences and shelter, it is altogether unsurpassed. The growth is rapid. If the peculiar growth of the Norway Silver or Black Spruce is noticed, it will be observed that when any one of the end shoots is cut off, two or three will sprout at the next joint to supply the want. Another great excellence is that the growth is only in the spring, so that you need not be pruning several times during the year, as is the case with some ornamental garden hedges, if you would have them look well.

If, when first establishing a homestead, we were to appropriate a few rods of ground for the purpose of growing these plants, together with Horse and Buckeye Chestnuts, Mountain Ash, Locust, and several more of the ornamental trees, the cost would be quite nominal, and in a few years we should have an abundance of the various kinds, to embellish our homes and defend them from the cold winds and frosts, as nothing will defend a garden border from early frost so much as a thick evergreen hedge close to it. The above seeds can readily be procured; but do not on any account trust to the Canadian variety of Spruce; they are worthless for the purpose of hedges, as they will not bear cutting, and get hollow and bare at bottom directly. No other kind will answer so well as the Norway variety.

C.

Selection of Seed.

One of the most important items of farm economy that calls just now for special consideration is the proper selection of seed wheat. Repeatedly during the last two years has the attention of farmers been called to this subject. The results of carefully selected seed have been very forcibly exemplified by the prodigious yields of certain new varieties of grain and roots, such as the Norway oats and Early Rose potatoes. The productiveness of these novelties has not been due to any particular quality of manure used, or any remarkably extra good land, but chiefly to renewed seed. I have myself seen Early Rose potatoes yielding fifteen to twenty good marketable potatoes from one single eye or set, and these potatoes were as large as eggs on the 8th day of June last, and were grown as ordinary potatoes in the open ground, and without extra culture in any way. There are many similar examples that might be cited, but these familiar cases will serve the present purpose.

The principle involved is further illustrated in the case of wild animals. These do not deteriorate or degenerate, notwithstanding the constant intercourse between relations, in fact re-sowing again and again the same seed; and why is this? Simply because the largest, strongest and most vigorous males are always masters, and the poor weakly members are driven away and not allowed to procreate the species. Were it not for this, wild animals would have become dwarfs long since. The law of nature which thus secures the perpetuation of the species in undiminished vigour and perfection is exemplified among the comparatively solitary beasts of prey, such as the lion, as well as among the gregarious tribes which multiply more rapidly, such as the wild deer of our own forests. These all have retained from time immemorial their original proportions and physical development. The only cause that has been found practically to influence size and power is scarcity of food, and occasionally this has exerted a deteriorating effect where civilization has encroached on the natural resources of the wild animal. Now, we may follow out the same train of thought, and apply it to the vegetable kingdom as well as to the animal. But in the case of vegetables there is no passion that compels the weaker to retire. The poor dwindled seed, therefore, so long as it retains its vegetative power, will produce its kind in abundance, but in constantly deteriorating quality. Hence it follows that, in our artificial husbandry, we should select all our best and finest productions for propagation, and reject all inferior specimens as utterly unfit for the purpose of reproduction.

The idea of changing seed is no doubt excellent, and the practice has often been found beneficial; but it may be questioned whether in these cases the benefit is not due to the superior quality of the new seed rather than the mere change. The selection has probably been carefully made from a farm of noted excellence, and more than usual careful culture has been adopted, so that a product of improved quality is secured. The benefit is, however, soon lost by the farmer who trusts alone to such a way of keeping up his supply. No doubt "like produces like," and a fine crop is often due to this course, though generally somewhat inferior to the sample sown; the succeeding crop will probably be reduced in quality and quantity, and ultimately all the original excellence will have disappeared. We need, then, some system, in order to keep up the good qualities of any sample. Admitting the benefit of a change of seed, admitting also that new varieties of seed from hybridization are often valuable, still the most important means at our command is the selecting the finest and best of the crop for the coming season.

Last harvest I carefully examined a crop of wheat, and with a pair of scissors cut off the upper portion of a great many ears. These were threshed out and put by. The middle parts were next cut off, and also threshed and preserved separately. The lower ends were then threshed out, and the samples compared. There was a manifest difference. The product of the top was equally plump, but much smaller, and moreover only contained two corns in a chest. The middle were full and plump, and contained three corns in a chest. The lower was a medium between the middle and top, better in sample than the top, but not as good as the middle; and also many of them had only two corns in a chest. Now, on counting the number of chests used and the number of corns produced, I found that the yield of the top was not only smaller in the size of the grain, but more than one-third less in number, and a proportionate decrease followed the lower parts of the ears compared with the middle.

Now, we cannot suppose that wheat grown during a succession of seasons from ears, or parts of ears, that contained two corns in a chest, would have the same tendency to produce three corns in a chest as that which had previously always grown the largest number. And it hence follows, that it is of great importance to grow that portion of the wheat ear for seed that had previously produced the best quality of grain and the greatest number of kernels. The true way to accomplish these very desirable ends is to follow the course I adopted; but this would involve so much labour that no field of wheat could well be grown from seed so obtained; but the results of a small lot so saved could be sown, and seed thus collected for another year.

Mr. Hallett, of the Pedigree wheat notoriety, has shown that the above ideas are quit correct, and has also for many years so increased the yield of wheat by these means that he once grew 108 bushels to the acre, as the greatest yield he ever obtained; 50 to 60 bushels were ordinarily grown, and 65 lbs. a bushel often attained. He went further; he selected all the larger ears, and from these he selected the largest kernels, and also in preference those specimens in which there were four grains in a chest, and by following out this system he obtained this enormous yield. But mark, not from exchange of seed simply, or any remarkably fertile land, but by adopting with plants the principle of reproduction among wild animals already alluded to.

All the new sorts of potatoes exemplify the same principle. Garnet Chilis now produce heavy crops, and the Early Rose still larger, and this increased yield is not due to the increased fertility of the land, but to the improved quality of the seed. Of course, food in abundance must be supplied to all plants, but manure and good culture are not the only means by which we can hope to increase our crops.

The course followed by one man in the township of Manvers has for many years been to obtain a sieve of just such a size as will allow all the smaller portions of his wheat crop to pass through, and all the larger and finer grains to be retained. He sifts his whole crop after this way, and always sells the siftings for flour, and retains the remainder, about eight-tenths, for seed, and his neighbours come for miles round to obtain it. He charges fifty cents a bushel more than the highest market price for his best seed, and never fails to sell all he has to spare.

Another way that was in use by one man for some years was called "thrown wheat;" many thought it named "throne wheat," but the name entirely originated with throwing the wheat on a long floor as hard as possible, with a small wooden shovel adapted to the purpose, and by which the large heavy grains of wheat went much further through the air than the light smaller ones. The man who first used this plan kept it secret, and made some money by thus selling his seed wheat, and attained a considerable notoriety, as the wheat was by many thought to be a new variety and very fine; but the plan soon was known, though its very simplicity caused it to be abandoned, or perhaps it is seldom practised because few have floors long enough, or indeed skill sufficient to throw the wheat to advantage.

To test the foregoing principles and practice, I would advise any one to procure a sieve, and by selecting their wheat as before described, out of 100 or 200 sifted bushels, they will obtain 50 bushels of very fine wheat, the growth of the middle portions of the ear, combining many of the requisites of a first-class seed. The cost is little, and trouble nothing; about a day's work will suffice to complete the sifting process; and when buying the wire gauze for the sieve, take a gallon of your wheat with you, and test the exact size required.

C.

Ploughing Stubble after Harvest.

We are inclined to think that there is not enough care bestowed on land that has just gone through the process of producing a crop of grain. It seems to be thought that once the harvesting is done, the husbandman's labours are ended on that particular piece till such time as he requires to use it again for the production of another crop, be that crop what it may. Farmers are too much inclined to look for present profit rather than endeavour to secure continuous prosperity.

The simplest operations of tillage are of more value and importance to the soil than most farmers are aware of. The more the soil is turned and exposed to the sun and air and the more its particles can be brought into contact with atmospheric influences, the more soluble and available becomes the plant food stored up in it.

Prof. Stockbridge, in a recent essay, says: "Silently and unseen, but surely and incessantly, are these agents accomplishing their appointed work. The frost of winter, with its crushing, disintegrating power, is reducing the rock particles to powder to prepare them for the more efficient action of its coworking agents. The heat of summer is decomposing the organic ingredients, and giving to the soil gases and acids for their secondary work. The air is permeating it with its oxygen to form acids and corrode and take to pieces its metallic elements; with its carbonic acid and ammonia to unite with other acids or alkalies in the soil, forming new and needed compounds. The moisture of the atmosphere is condensed to rain, and, descending to the earth, carries into the soil its gases for plant food, and dissolves the material prepared by the other agencies."

But this is not the only benefit to be derived from keeping the soil as much under tillage as possible, when it is not either occupied by crops, or locked up in the grim embrace of the frosts of winter. The soil is more or less full of the seeds of foul weeds, and the pupæ of grain-destroying insects, which can be in a measure diminished, if not destroyed, by tillage operations. We know it is usual to consider that the stubble fields are worth something as pasturage for stock, and to turn the poor beasts into them for a while till the pastures proper become recuperated. They doubtless manage to pick up a living, and for the first week or two may thrive passably well with the help of the fallen grain; but in many cases the animals come off them in a worse condition than if they had been kept on the pastures. If, instead of this being done, the stubbles, where not seeded down, were ploughed up, scarified with a gang plough, or by a cultivator, within two weeks after harvest, the work being so shallowly done as not to bury the weed seeds on the surface too deep, there would be heat enough to start germination of those seeds, yet not time enough for the plants to grow up to a second seeding. Even harrowing the stubble, provided a very heavy sharp-toothed harrow was used, would, in those cases where the soil is not too heavy or compact, accomplish this end. When the land is much infested with the midge, ploughing to a moderate depth, say five or six inches, and turning the furrows wide and flat, would throw most of the midge pupæ so near the surface that the birds would destroy many of them, and the frost, if severe in the fall, would put the remainder out of the way of doing much injury the coming season.

A Backwoods Farm—An Old Settler's Experience.

It may not be uninteresting to many of our immigrant readers to have portrayed before them the history of a new farm in the backwoods, comprising about five hundred acres. The following narrative, having been compiled from actual experience, is entirely reliable, and cannot fail to prove valuable to new settlers, who, whilst reading the record of some failures, can at the same time revolve in their own minds the course they would have pursued under the same circumstances. By this means many mistakes may be avoided, that the writer of these reminiscences occasionally fell into. Of course, he had many successes and triumphs, and also some reverses; and, when a truthful account is given, the reader can have the benefit of all the experience thereby gained.

As the history extends over nearly twelve years, it must necessarily require more than one or two articles; but we think we serve the interest of the farming community in general, and that of the immigrant in particular, by allowing space for the interesting record.

ED.

LOCATING AND CHOICE OF LAND.

Our first task was carefully to examine the tract of five hundred acres of land we contemplated purchasing. We hired a surveyor, and under his direction and guidance we walked over the land backwards and forwards almost all one day; and since that time, and now that we have the farm almost all cleared up, and have learned to know every hole and corner, tree and shrub on it, we can fully appreciate how little we were clearly enlightened by walking over the land. To test the quality, we were told to examine "turn-ups," that is, upturned trees, and found about eight or ten inches of dark soil, and below that a subsoil of clay,

mixed with small limestone gravel, a large portion of which adhered to the superstratum. The gravel appeared to be mixed with the clay in the subsoil in about the same proportion that the raisins in a poor man's pudding bear to the pudding itself.

We saw that the land generally, although it appeared rich, and was all covered with the best hardwood, was what is called "cradle-knolly," and at that time we did not understand the quality so developed. We now know that "cradle knolls" are a sure sign of a poor, wet subsoil, no matter how rich the surface may appear to be, as otherwise the trees would have gone deeply into it, and by consequence would not have been so readily uprooted in previous years. For the fact is that the roots of trees do not like to penetrate into such a sour, hard, uncongenial portion of the land, and consequently, by spreading out on the surface, and not penetrating deeply, they were continually being uprooted in all directions. Year after year, as the timber had attained its growth, and each uprooted tree had drawn with its roots the surface soil, and with it some subsoil adhering—the roots themselves, meanwhile, decaying in their turn—the earth so gathered had accumulated into heaps or knolls, to be again occupied with a new growth of timber. And so these cradle knolls are formed, and the subsoil, thus drawn into heaps, has left deep depressions or hollows in the intervals. These intervals were very rich, as the wind had many a time drifted them full of leaves, and of course had denuded the higher spots in the same ratio, thus leaving the elevated spots poor, and the lower ones too rich and wet.

When, therefore, in subsequent years, we succeeded in ploughing away the high spots, and thus levelling the land, we actually in the process covered up the best soil with the poor and exhausted knolls; and thus we found to our cost that "cradle-knolly" land must necessarily be comparatiually poor for some years, and until the gradual mixture of hillock and dale was ultimately equalized by cultivation.

Here is an explanation to emigrants coming to Canada well worth their careful attention, as, independently of the causes above stated, the "cradle-knolly" land should be taken up with caution. The extreme roughness of its surface renders it three times as difficult to plough before the roots are decayed; and during wet seasons the water is sure to lie in the hollows, to the injury of the crop. And again, the roots of trees in the kind of land above described, which do not go deeply into the soil, but rather creep about near the surface, offer a terrible obstruction to ploughing during the first six years after clearing. We have often, since those days, seen land where the tree roots penetrated the subsoil so nearly to the stump that the plough could be conveniently used years before it could in our case.

Surface Application of Manure.

It is now becoming generally understood that the old plan of ploughing barnyard manure into the soil is not the most advantageous plan that can be adopted to secure its being eliminated as plant food by the crops to be grown on the land. As years pass on, and more experimental observation is taking the place of old faith in the doings of our forefathers, among the agriculturists, it is being demonstrated by practical experience that much of the success in applying manures to the soil will be dependent upon the art used in adapting the method of application to the circumstances of the case. The natural tendency of all manures applied to the soil is to work downwards; that is, the elements of plant food contained in them, as soon as set free by the action of water, which in all cases is the greatest resolvent, are carried beyond the reach of the roots of plants, unless they can be placed in a position to be made immediately available as plant food, by being taken up by the roots of the crop as fast as they become resolved into their chemical constituents. This course of action is constantly going on from the time the manure is first deposited in the yard, until it is finally taken up as food by the plants in the soil to which it is applied. This action may be accelerated or retarded, according to the method adopted in managing the material of which the manure is composed.

Now, if we apply the manure in a long undecomposed state to a stiff clay soil, and turn it under deeply with the plough, it will remain inert in the ground for a length of time, perhaps for years, according as the soil is worked or not afterwards, and its good effects will be divided over several successive crops, giving but a small proportion to each, as being deeply buried in a compact soil, it will not quickly be changed into plant food. Suppose, instead of being so buried, it was spread over the land late in the fall, and allowed to remain all winter, to be turned under with the plough early in the spring. The fall rains and winter's snows would wash every particle of available plant-food then in it into the surface soil, for some distance down, where it would be retained in solution, and go to help forward the crop to be grown in the succeeding summer, during its early stages. The inert material then left to be turned under by the plough in spring would be gradually decomposed under the surface, and become available either for the crop in its later stages of growth, as its roots penetrated into the soil, or for the succeeding crop, when the reversal of the soil would throw the partly or wholly decomposed materials again towards the surface.

Now, if we have the ground prepared and ready for a crop, and have on hand some barn-yard manure already in a state in which a large proportion can be readily dissolved by rain and washed into the soil, it would be of vastly more benefit to that crop if the manure were spread over the surface, and harrowed in with the seed, than if it were buried out of sight with the plough. What would remain on the surface of undecomposed elements would be of no more value were they buried out of reach of the roots of the crop to be grown, but on being turned under at the next ploughing, and again turned back before the next crop is sown, they would become converted into available plant food for that crop. In applying barn-yard manure to the turnip crop, it is found the best plan to run furrows with the plough, fill them with green manure, and cover that with a light coat of earth, on which the turnip seed is sown. The roots of the turnips penetrate to the manure, and extract all the then available plant food in it, leaving the remainder to be decomposed by time and fermentation, to be made available for the next crop, when most of the manure will be turned up towards the surface, in a condition ready to have the fertilizers contained in it washed by rain back into the soil, among the roots of the grain crop that usually (under a proper system of rotation) succeeds a root-crop.

It is an old fallacy that by applying manure on the soil, much of its fertility is wasted by evaporation. This is not, and cannot be the case, unless to a very limited extent with a single constituent, namely, ammonia, and it may be questioned if anything more than the water contained in the manure can be evaporated, leaving the salts held in solution by it behind, to enrich the soil, when again dissolved.

The only advantage gained by turning under manure with the plough is the acceleration of the decomposition of the straw and other fibrous material contained in it, which in course of time become gradually resolved into plant food by the chemical action of the mineral salts contained in the soil.

Superphosphate of Lime.

W. G. S., of Toronto, wishes to know how to make superphosphate of lime. We presume he refers to the home-made article, and not to the commercial fertilizer. A ready way of manufacturing this important manure is to break up the bones as fine as possible, and then place them in a wooden box or barrel. Water, equal to about one-sixth the weight of the bones, may next be added, well stirred in, and left for a day or two, to heat and ferment. Boiling water would be best for this purpose. Then add sulphuric acid, mixing well with a wooden spade (no metal should come in contact with the mixture) in the proportion of about forty pounds of acid to one hundred pounds of bones. Let it stand for about two weeks, stirring daily. If the mass is not then dry, add some absorbent, such as sawdust, dry

earth or peat; but on no account use for this purpose lime or ashes.

Thus made, the compound will be a valuable manure, which may be kept for a long time without losing its strength; but it should be protected from exposure to wet.

A good manure may be made from bones without forming a superphosphate, by dissolving the animal matter of the bone by means of alkaline leys, and thus freeing the bone earth, which is then in excessively fine particles fit to be dissolved in the waters in the soil. Many recipes have been given for this. Dr. Nichols, in his Boston *Journal of Chemistry*, February, 1869, gives the following, which he recommends: Take a barrel of fine ground bone and a barrel of good wood ashes, mix well together and add three pailsful of water; mix the whole intimately, stirring daily; the mass will be fit for use in a week.

Hop Picking and Curing.

To the Editor.

SIR,—As it may interest some of your numerous readers, I take the liberty to give you a rough sketch of the process, as seen by myself, and learnt from the managers of the large yards in Waterloo, which I have visited.

The picking is done by women and children, who are waited on by men called tenders, who cut the vines, pull the poles, and bring them to the boxes, where they are soon stripped by the pickers, after which the poles are stacked up for the next year's use. The pickers are paid by the box, and can earn 50 cents to 75 cents a day, according to the nimbleness of their fingers.

The hops are emptied from the boxes into large sacks, and carried to the dry-house, where they are immediately placed on the slat floors of the kiln, which are heated by large stoves, with long strong pipes running across the room under the slat floors. The hops are dry in about sixteen or twenty hours, and are then shoved off into the store-rooms, where they lie until cool. When they are ready for the press, they are pressed into tidy bales by strong lever presses. The sacking is first laid on the bottom of the press, then strong, wide sheets of paper; the press is then set up and trodden full, when another piece of sacking and paper are placed on the top, and the follower put on and pressed down The sacking is sown together after the sides of the press are taken down, the follower and standards holding it secure and giving room for sowing.

This putting paper inside of the sacking is a new improvement, claimed to answer the purpose of preventing evaporation and the injurious effects of light. As paper is a non-conductor, and air-tight, it is thought to answer admirably.

The crop in Western Ontario is estimated at about three-quarters that of last year, and of about the same quality.

C. G. B.

Waterloo, Aug. 30, 1870.

Saving Corn Fodder.

The deficiency in the hay crop this year will be considerable in some places, and it would be well for farmers who have crops of corn to take a little extra pains in saving the stalks in such a way that they will keep over winter, and yet retain sufficient of the saccharine juices to be palatable as food for stock.

To do this the corn should be cut as soon as the ears are well filled and glazed, and, if possible, before frosts come. Then set up in shooks for a week or two, and husk out the corn. That done, the stalks should at once go under cover, and be stowed away standing up, if possible, or in such a manner as will prevent them from getting too compactly together, and becoming mouldy from heating. Corn stalks cut up and steamed, or mixed with cut hay and a little meal, and wetted slightly at the time of feeding out, are much preferable as food for cattle to straw or poor hay. Corn sown in drills for fodder, and cut and cured before frost comes, is most excellent and nutritious food for milch cows.

Remedy for the Prevention of the Turnip Fly.

The following top-dressing for preventing the ravages of the turnip fly was stated by the late Mr. Fisher Hobbs to have been used by his steward for many years with perfect success.

One bushel of white gas ashes, fresh from the gas-house, one bushel of fresh lime from the kiln, six pounds of sulphur, and ten pounds of soot, well mixed together, and got to as fine a powder as possible, so that it may adhere to the young plant.

The above quantity is sufficient for two acres when drilled at twenty-seven inches. It should be applied very early in the morning, *when the dew is on the leaf*, a broadcast sowing-machine being the most expeditious mode of distributing it, or it may be sprinkled with the hand carefully over the rows. If the fly continues troublesome, the application should be repeated; but Mr. Fisher Hobbs stated it had never failed where applied at night to Swedes, turnips or rape.—*Gardener's Magazine.*

TREES CONDUCIVE TO HEALTH.—By absorbing or emitting electricity, according as it is deficient or in excess, they (the trees) maintain a natural electrical state of the atmosphere around them, and we all know how intimately atmospheric electricity is connected with disease. Without trees there is always a deficiency of electricity, consequently a deficiency of ozone, and the air is not in its naturally healthy state. They act in like manner as regards heat, cooling the atmosphere at eventide during the hot summer months by rapid radiation into space, while streets and squares without trees remain hot and close.—*Scientific Review.*

Cheap Farm Gate.

A correspondent in the *Journal of Agriculture* gives the following directions for making a good gate at small cost and trouble:—

Take six pieces of stuff ten feet long, four inches wide, and one inch thick; lay these down on a level piece on the ground, leaving your first bottom space two and three quarter inches wide, the next three inches, the next three and a half inches, the next five and a half inches, and the next, or top space, nine and a half inches wide; then take the same kind of material and nail across the ends with annealed nails; then nail on a cross brace from the upper to the lower corner, also with annealed nails, so that it will fit neatly inside of your end pieces. Now turn your gate over, and nail similar upright pieces across the ends, even with the ones on the opposite side, and one upright piece midway between the ends. This latter is far preferable to putting on a diagonal brace on that side. In such a gate there is no morticing, and, for the weight of it, it is far stronger than any morticed gate that can be made.

Annealed nails, to my mind, are better than wrought nails. If you use inch stuff, common eightpenny nails are heavy enough, as they are two and a half inches long, and half an inch is enough to clench. The best way to anneal them is to put them in the stove while the folks are getting supper, cover them up in the hot ashes for the night and take them out next morning. This slow cooling serves to toughen them. To get the proper anneal, you should heat them to a white heat, but not enough to blister the iron. I find it better to drive the nails clear through, and clench them after they are driven, as in this way a neater clench is made.

Such gates as I have described look well, and are very quickly made. A good hand will put up five of them in a day—make them I mean, not hang them also. In hanging your gate, place the opening end at least one and a quarter inches above what you wish it to be, as any large gate, no matter on what kind of a hinge, will spring at least that much.

Indian corn, owing to the warm weather of June and July, has reached an extraordinary growth in the county of Lennox, and the present season is likely to be the best for that article that has been seen in many years in that section. The Napanee *Standard* says Mr. Jacob Schryver, of North Fredericksburgh, has shown a stalk which measures 10 feet in height, and says a large field from which it was taken will average about the same. Mr. D. Jennings, of Camden, also brought in some stalks measuring 9 feet 9 inches.

Stock Department.

Sundry Breeds of Swine.

In "Harris on the Pig," we find descriptions of some breeds of swine that are as yet unknown in Canada, and might be introduced with advantage for the purpose of improving the general class of those we already have by means of judicious crossing. Among the English breeds are two, named respectively "Cumberland" and "Small Yorkshire." The former is a somewhat coarse white breed, having no very high qualities of excellence about it except hardiness of constitution.

THE SMALL YORKSHIRE is a white breed peculiar to Yorkshire, and has many points of excellence. It has a short head and small erect ears, broad carcase, deep chest, small short legs, and fine bone. It is spoken of as being always ready to fatten and turn to account, either in the way of roasting pigs or small porkers. Three or four of them will keep well and fatten on the food which would barely suffice to keep one of the large Yorkshires.

THE YORK CUMBERLAND BREED.—By a judicious crossing of the above named two breeds, and perseverance in the cross, a breed has been obtained that combines the size of the Cumberland with the quality and symmetry of the Small Yorkshire. This has now been established as a distinct breed, under the name of York Cumberland, and seems to be carrying all before it at the shows in England as prize winners in the white classes. It is said of them:—"No animal of the pig species carries so great a proportion of flesh to the quantity of bone, or of so fine a quality, or can be raised at so small a cost for the pork made." The ordinary weight of these pigs, when slaughtered, at ten to twelve months old, is from 280 to 340 pounds dressed, but it is said they can be profitably got up to 600 pounds each, where large thick bacon is desirable. It is said to combine size with early maturity and aptitude to fatten, in a very remarkable degree.

THE WHITE LEICESTER.—This is another breed of which as yet but little is known. They are a medium breed, white in colour, averaging about 300 pounds each when fatted at a year old. A pair of them carried off the prize for pigs at the Paris Exposition, and a pair of them, that weighed 180 pounds each at 18 weeks old, carried off the gold medal at one of the Smithfield Club shows.

IMPROVED OXFORDSHIRE.—This is a black breed, produced from a cross of some Neapolitan boars on Berkshire sows, afterwards adding a dash of the Essex by using Essex boars from Fisher Hobbs to breed the sows of the cross to. The produce has been quite a hit, and has proved very successful at the Royal and Smithfield Club shows, as well as local ones. These pigs are of fair size, quite black, well covered with hair, very prolific, and good mothers and nurses. They are said to be remarkably healthy. They are especially adapted to dairy farms, and pork butchers, as they are said to give a larger proportion of lean to the fat than any other breed, and to be always in condition to kill for porkelets. At sixteen weeks old they will dress 90 pounds, at 9 months 220 to 280 pounds. With extra feeding, they will attain 400 pounds before they are a year old.

CHESTER COUNTY WHITES.—This is an American breed that originally appeared in Chester county, Pennsylvania. Mr. Harris appears to doubt if they are yet thoroughly established as a breed, but says the sows are admirably adapted to cross with boars of the refined English breeds. They are white in colour, and rather large in size, averaging about 500 pounds each at sixteen to eighteen months old. Some older specimens have gone to 900 pounds. They are hardy, strong, and vigorous, have good constitutions, and breed well, the sows being good mothers. They are heavy feeders, and require time to reach maturity and fatten well. Harris says:—"There are probably families among them that have been bred long enough together to permanently establish their good qualities. But it is certain that many Chester Whites have been sent out, that produce litters the pigs of which differ from each other as widely as the litters of common sows, and far more widely than the litter of a common sow got by a thoroughbred boar." Paschal Morris, of Philadelphia, who has bred them for many years, and probably knows as much about them as any one, says of them:—"There is a considerable misapprehension about this breed. It is constantly forgotten that it is not an original, but a *made-up* breed. They differ from each other quite as much as any one known breed differs from another." This, coming from such a source, is pretty good evidence that the Chester Whites are not an established breed, and can only be used to advantage in the same way as the common swine of the country, that is, to raise cross-bred pigs from, by putting the sows to a Suffolk or Berkshire boar, and thus obtaining pigs of a finer quality, earlier maturity, and more aptitude to fatten than the mother, combined with her size and strong constitution.

THE JEFFERSON COUNTY BREED.—This is a large white breed, originated in Jefferson county, New York State. For a dozen years past they have carried off all prizes at the New York State Agricultural Fair, against the Chester White and every other large breed. We saw several of them at the Fair at Elmira last Fall, and for their size they were the finest and handsomest pigs we ever saw of the white breeds. It is supposed that they originated from a cross of a boar imported from Yorkshire, probably a Small Yorkshire or York Cumberland, on a large sow of the old Cheshire breed, said to be the largest of the old English breeds. At first, it is said, they were very large, but rather coarse, but since then they have been bred more towards an approximation to the fine bone of the Small Yorkshire, or, probably, York Cumberland. They are still large, though not equal in size to the Large Yorkshire, but with very different characteristics. Their heads, in proportion to their size, are the smallest we ever saw on a pig; the ears are small and fine, pointing upwards and forwards, cheeks very full, bodies of great length and very compact, legs very short and small. They have very small bone indeed for such large pigs. They are as much superior in quality to the Chester White as any pig can well be. The breed, coming as it does from a cross of two pure breeds carried through several generations, may now be said to have become established, and certainly the young pigs we saw with some of the brood sows at the Fair were of most uniform type throughout the litter, and as perfect in form as could be desired. Boars of this breed would doubtless be found of great value to cross on other large breeds, especially the Chester White, when it is desired to retain size while improving quality. That this breed has derived its best qualities from the Yorkshire blood is admitted by those who have bred it longest.

THE MAGIE BREED.—This is not yet an established breed, though it may ultimately become so. It originated in Butler County, Ohio, from a cross first of Poland and Byfield, afterwards again crossed with some breed called Big China, which was probably a large variety of the once well-known Chinese hog. All these were spotted breeds. Somewhat later some Irish Graziers, a medium-sized white pig, of fine quality and great aptitude to fatten, were imported, and used much to cross on the already improved cross-bred hogs of Butler County. Lastly, the Berkshires were brought in, and were freely used in crossing upon the then existing stock. By careful selection, and breeding from the very best animals produced from these various crosses, Mr. David M. Magie thinks he has succeeded in producing a hog that as a breed may be said to have become established. This is, however, doubtful, and we should not yet be inclined to place much reliance on their fixity of character. These hogs, so far as published statements of their weights go, do not seem to be anything extra, either as regards size, or early maturity. Their average weight, when fatted and slaughtered, at eighteen months old, is given as 450 pounds, which is no more than we should expect from good cross-bred pigs out of a large common sow by an Essex or Berkshire boar. They seem to be a close approximation to the Berkshire, but with larger carcases and heads, and coarser bone. They might be greatly

improved, and perhaps increased in size, while reducing the offal, by using large Yorkshire boars of the very finest quality of bone that can be had.

The demand for very large hogs, however, is not now such as it was. Pork packers and bacon curers find it more profitable to encourage the raising of hogs of a medium size, say 250 to 350 pounds dressed weight, rather than larger ones. These very large hogs require more food in proportion to weight, to carry them through, than smaller and finer-bred ones do.

Cattle Feeding.

Mr. M'Combie, of Aberdeen, Scotland, one of the most eminent and successful of British feeders, in his recently published work, entitled "Cattle and Cattle Feeding," tells much that is valuable and interesting. Speaking of buying store cattle to be prepared for feeding, Mr. McCombie claims that animals that have been brought up on anything of a forcing system, to induce a large development at an early age, contrary to the general impression are not the ones that can be most profitably used to be fed for the butcher. He says "an animal well bought is half sold," by which he does not mean that a low priced one is to be preferred, nor yet one already half fat, but one that possesses the best points nscessary to ensure the making of a moderate amount of first-class beef on a small amount of food—in other words, an animal that has a kindly disposition to take on flesh and produce meat of a uniform good quality throughout the carcass. He gives the preference to those that have been raised in the poorer districts, kept through the winter in straw yards, with the addition of a few roots, having the run of common pasture during summer, with abundance of exercise, till they are fully grown, say four to five years old. He buys these in spring, takes them to where they can have a good range of richer pasture for the summer, just enough to fill them out with flesh, and as soon as the pastures are done and the time for housing comes, at the approach of cold weather he puts them in the byres, and commences the process of feeding by giving hay, roots and meal, gradually at first, for months together. As soon as they reach the point where no more flesh can be profitably put on them, they are crowded up on oil cake till they become "ripe," when they are sent to Smithfield market. The object aimed at is to make beef that is termed "marbled," i. e. the fat and lean thoroughly blended together throughout the carcass. This is the kind of beef that is most valued, and brings the top price in British markets, and gives the rich, juicy sirloins, ribs and steaks, that make the roast beef of Old England so justly famous the world over.

Americans have not yet reached a nice point of discriminating in judging of the quality of the meat they consume, and so our butchers are not able to offer the same inducements to feeders to undertake and continue the process of feeding in the same way as is done in Britain. Here the idea seems to be to put the fat all on the outside, and into the form of tallow, which can be cheaply and quickly done by feeding Indian corn, either whole or ground. By the time the animals have been fed on corn from two to four months, they will, even though thin in flesh, have quite a layer of fat between their ribs and hides, and sell readily as first-class beef, though the meat when cooked too often proves stringy, tough and oily. Time will doubtless work a change in our manner of feeding cattle for winter beef, but not until by the introduction of a really first-class article into the great city markets, the consumer will discriminate sufficiently to enable the butcher to pay such prices as will encourage feeders to take more time and pains to carry out the art of producing beef that will reach the standard of excellence attained in Britain.—*Country Gentleman.*

A correspondent informs us that in the County of Brant an application of one part of carbolic acid to five parts of linseed oil has been found efficacious in the treatment of the cattle fly ailment.

Veterinary Department.

Flies on Cattle.

Considerable alarm has been excited in many parts of the country by the reports of a terrible cattle disease that had made its appearance, and had even, according to some accounts, proved fatal in many instances. We have personally investigated a number of these cases, and have also received letters from veterinary surgeons in different parts of the country, who quite concur in our own view of the matter. We have no hesitation in saying that all these cases of so-called cattle disease that have yet come under our notice are due to the attacks of flies, that at this season terment cattle, horses, and dogs. These insects have made their appearance somewhat earlier than usual, and have abounded in unprecedented numbers. The irritation and suffering they inflict has consequently been more than commonly serious. They puncture the skin, and produce irritable sores, which set up inflammation, swelling, and sometimes considerable constitutional derangement. It is quite possible that in severe cases among feeble animals a fatal termination may have resulted, but we have no doubt that in a large proportion of fatal cases death has been caused by some other complaint. There is therefore, we feel confident, no cause for alarm, and no insuperable difficulty in dealing with the "plague."

The methods of combating the evil are preventive and curative. To ward off the danger, we recommend that, as far as possible, cattle, as well as horses, should be housed during the day, and only allowed to feed in pastures at night. The stables should be kept as cool as practicable, and comparatively dark, with thorough ventilation and the strictest attention to cleanliness. The manure should be removed frequently and to a distance.

The flies are more numerous in low, wet meadows than in dry pastures, and it is probable also that wetting the skin, as the animals do by standing in the water, and subsequent exposure to the air, has a tendency to promote cracks and sores, just as a similar transition will produce in the human subject chapped hands and the like.

The practice of soiling animals during the day, instead of pasturing them, has other advantages besides protecting them in a measure from the evil under consideration, and has been found eminently economical in saving food and storing manure.

The curative treatment to be adopted consists in first washing the parts thoroughly with soap and water, and if there is much inflammation, fomenting with warm water. Afterwards apply with a feather a lotion consisting of equal parts of oil of tar and tincture of benzoin. Or a similar application may be made of impure carbolic acid, diluted with six parts of water to one of acid.

Flies on Horses.

Carbolic acid soap seems to be a most valuable remedy for most of the troubles and annoyances to which farm stock is subject. We have heard of so many wonderful cures and benefits rendered by it that we are beginning to be quite enthusiastic over it. As a sheep-dip, as an exterminator of vermin, as a plant-wash, as an ointment for galls and sores, in fact, as a remedy for almost every farm trouble it has proved successful. A friend of ours a few days since, being obliged to drive a valuable horse twenty or more miles, and knowing that flies would prove troublesome, conceived the idea that a wash of carbolic acid soap-suds over the entire coat of the horse would protect it from flies. The wash was applied, and through the day, although myriads of flies swarmed about the horse, and even alighted on it, not one made an effort to draw blood.

Now, with a remedy against these pests so easily available (a large piece of the soap costing but a few cents, and procurable at almost any drug store), there is no excuse for neglecting to provide it. Let a pailful be made and kept standing in the stable. Whenever a horse is to be taken out, either for the road, field or pasture, dip a sponge into the suds and moisten the animal's coat with it. The time required would not be a minute, and the cost not a cent, but the benefit rendered to the animal would be very great.—*Mass. Ploughman.*

Ergotized Grass.

To the Editor.

SIR,—I have frequently noticed during the present season that the seeds of some kinds of grasses, in meadows and pasture lands, have in some way deteriorated, or been superseded by a peculiar excrescence, which I suppose is caused by a parasitical fungus. I herewith forward sample. Will you have the kindness to inform me what is its nature and properties, and in what manner it will affect horses and cattle, which eat of it? Some farmers suppose that it is causing their horses to have a species of distemper with severe cough, which may lead to the heaves; others believe that it is affecting the blood of cattle, and gives them the hoof ail. In fact each has his theory, and various injurious results are imputed to it.

W. M.

Port Burwell, 1st August, 1870.

Reply—The sample sent is a specimen of ergotized grass, caused by a fungus somewhat analagous to the ergot of rye. If taken to any great extent, such feed is likely to prove injurious, either to horses or cattle. As to producing the specific diseases mentioned, we can scarcely hazard an opinion, but we have no doubt whatever that the disease known as heaves in horses, in many cases is the result of improper feeding, and especially using inferior kinds of hay, which appear to have a peculiar and injurious action upon the pneumogastric nerve.

Hoof Ail.

To the Editor.

SIR,—Please inform me of some successful plan for treatment of the hoof disease in cattle. During spring and early part of summer, I lost eight cows from my herd, several of them very valuable animals, and all in good condition. The first symptoms were slight lameness in the hind feet, which gradually increased without much swelling, until considerable exertions were required to make the animal stand at all. Soon after a fissure, varying in depth, would be observed encircling the feet at their juncture, and increasing daily in depth, without sloughing, until the entire removal of the hoof was effected, leaving the animal only the ends of its legs, with bones protruding, to stand upon. They become quickly emaciated, and soon succumb to the disease. In a few cases of those I treated, I met with partial success, but some of the animals are still quite lame. I hope that yourself or some of your numerous readers can give me some information on this subject.

A SUBSCRIBER.

Port Burwell, 1st August, 1870.

REPLY—The treatment of such severe cases of hoof ail as described above cannot be undertaken with any great success. The severe inflammatory action which causes a separation of the sensitive and insensitive structures should be allayed by the use of poultices, and placing the animal in a comfortable stall, which must be kept clean; if the toe of the hoof is unnaturally long, it should be cut off, as the extreme length of toe throws a greater strain upon the coronet. Whenever an eruption is observed, the parts should be dressed several times a day with carbolic acid lotion; the patient must also be allowed a liberal supply of the best food. One drachm of the iodide of potassium might be given once a day. In many cases it may be found necessary to use the knife and remove any detached horn; and, if any matter forms, a free exit must be given, otherwise the imprisoned matter will act as an irritant, and soon lead to a separation of the laminæ.

Veterinary Queries.

To the Editor.

SIR,—Will you please inform your readers whether the Charlier horse shoe has been tried in Canada and found satisfactory? Also give some description of the new Baltimore shoe, which is easily removable.

Is there any application (as glycerine) which will obviate the brittleness of hoof caused by standing on plank floors?

It is said that in England grass is cut early for young racers, and saved in a peculiar manner. How is it done? and would it not be good for other horses?

Books tells us that sows will always breed three days after farrowing. I have kept pigs for several years, but never had one to come sooner than three weeks.

J. C.

Orillia, July 20th, 1870.

REPLY.—We are not aware of the Charlier method of horse-shoeing having ever been tried in Canada. It is losing favour in Paris on account of its expensiveness. We cannot give you a description of the new Baltimore shoe.

Brittleness of the hoof is prevented to a certain extent by standing a horse for a couple of hours daily in moistened clay; the application of a hoof ointment composed of oil of tar one part, to eight parts of lard, is also attended with benefit.

If a certain kind of hay is good for race horses, it follows as a matter of course it must also be good for horses of another description. We believe that hay contains the greatest amount of nutriment when cut early before ripening takes places, and no doubt haymaking, like everything else, is better done in some parts than in others. English race-horses are usually fed on hay that is one or two years old.

Your experience with regard to sows breeding is the ordinary one. Instances of an earlier conception are exceptional rather than common.

Swollen Udder.

To the Editor.

SIR,—During the last two months our cow has been seriously afflicted with a swollen bag. As the swelling subsides, we get stringy or curdled milk from one or more teats.

If you know of any remedy, you will confer a great favour upon us by inserting it in your widely circulated paper.

A SUBSCRIBER.

July 1870.

REPLY.—Swollen bag, or inflammation of the udder, is usually best treated by cold applications. Apply a broad web of cloth around the cow, and cut holes in it to keep out the teats, then place some tow between the cloth and the udder, and keep it constantly moist with cold water. Give a good dose of purgative medicine, as three-quarters of a pound of epsom salts, dissolved in three quarts of water. When the swelling subsides, hand rub the udder several times a day, and give internally one drachm of the iodide of potassium daily for eight or ten days. The cow should be kept in a cool box or stall, and not exposed to the hot sun.

The Dairy.

Salting Dairy Cows.

The importance of salt for dairy cows is generally understood, but nevertheless it is much neglected. And where a quantity sufficient for a certain number of cows is supplied, it frequently happens that, from the manner in which it is fed, some animals get more than they require, while others obtain little or none at all. A late number of the *Rural New Yorker* has the following article on this topic:—

"The way to salt dairy cows is to have the salt conveniently located for stock where daily access may be had to it, and the animals allowed to take whatever their appetites crave. It may be placed in boxes arranged along in the feed alley of the stable, or in the troughs in the shed, or yard. When cows have free access to salt, they soon regulate their appetite to the daily use of small quantities of it, taking no more than is required to promote good health.

"Animals require more or less salt, according to the character of their food, and the practice of salting at certain intervals is often injurious, since they are liable to over-feed of it, causing excessive scouring and derangement of health. This is particularly the case when salt is thrown out to stock indiscriminately in the field at intervals of a week or more. In such cases, the master cows not unfrequently gorge themselves, preventing the weaker animals from getting a due supply, and thus one part of the herd is injured by over-eating, and the other part from not obtaining what is needed. When the animals have free access to salt, nature dictates as to its use, and hence, good results both as to health and the yield of milk follow.

"Salt is very necessary for milch cows. Without it the milk becomes scanty and imperfect. It is an important element in the blood, and furnishes the soda necessary to hold the cheesy part of the milk in solution. Maidlen found, in his analysis, 1,000 pounds contained nearly half a pound of chloride of sodium. There was also one and three-quarters pounds of chloride of potassium. There are various purposes in the animal economy that require salt, and cows in milk should at all times have free access to it.

"Perhaps the greater necessity for its use is in Spring, when cows are first turned to grass. The feed then is rather deficient in saline matter, and does not furnish sufficient for a large quantity of milk. As the grass becomes more mature, the mineral elements are more abundant, and there is less desire on the part of animals for salt. It is on this account, and because cows have been dried of of their milk, that in Winter much less salt is required in the dairy than in Summer. From experiments that have been made, it has been found that in May and June, when milch cows have been deprived of salt for several days the milk shrunk from one to two per cent. in quantity, and from four to six per cent. in quality. Later in the season the experiments showed less difference.

"Thus it will be seen, that dairy stock, to produce the best results, should have a daily supply of salt, and the quantity is much better regulated by the animal than it can be by the stock-keeper who doles it out at intervals.

The Production of Cheese.

It is estimated, says the New York *Mercantile Journal*, that there are in the United States and Canada 1,000 factories, whose average production is equal to 117,250 boxes. The cheese made in the United States and Canada in 1867 reached 215,000,000 lbs., and in Great Britain, 179,000,000 lbs. The consumption in America during the same period amounted to 160,000,000 lbs., and in Great Britain to 400,000,000 lbs., leaving a deficiency over the joint-production of the two countries of 75,000,000 lbs. This deficiency was supplied by Holland and Belgium. The principal States engaged in the manufacture of cheese in this country are New York, Vermont, Massachusetts, Pennsylvania, Illinois, Ohio, Michigan, and Wisconsin. Western New York, the Western Reserve, and some sections of Illinois and Michigan, enjoy a deservedly high reputation for the excellent qualities of the products of their dairies. England has long been justly celebrated for the abundance and superior quality of its cheese. Cheshire, Stilton, Derbyshire, Suffolk, and Cheddar, are the best known varieties. Gouda cheese, the best made in Holland, is very pungent, which preserves it from mites; and this pungency is attributed to the fact, that muriatic acid is used in curdling the milk instead of rennet. Parmesan cheese, made at Parma, in Italy, owes its rich flavour to the fine sweet herbage of the meadow along the Po, where the cows are pastured. The best Parmesan cheese is kept several years, and none is sold until it is at least six months old. Swiss cheese is made, in part, of skim-milk, and is flavored with fragrant herbs. They usually weigh from 40 to 60 lbs. each, and are exported in casks, each of which contains ten cheese. Westphalia cheese derives its flavour from the curd being allowed to become soured before it is compressed. Dutch and Swiss cheese contains, according to chemical investigation, from 26 to 40 per cent. of nitrogenized matter, considered the most nutritive constituents of food. The best cheese is from 22 to 100 per cent. more nutritious than bread and meat, which contain only about 22 per cent. of nitrogen. The superior qualities of cheese have been repeatedly proved by the experience of labourers in those countries where it forms one of the principal articles of food. To delicate stomachs, cheese is objectionable, on account of its slow and difficult digestion; but to individuals of great physical strength,

it is a healthful and agreeable article of consumption. In combustible or heating qualities, cheese is only exceeded by oil, butter, and like unctuous substances.

Butter for Winter Use.

Mary A. Lee, of Cain, Pa., writes to the American Institute Farmers' Club on the subject of making butter for winter use. She says that butter made in October and November, if good, may be kept so by printing in small table prints, and sprinkling each with salt, and laying loosely in a stone jar. To keep butter good that is made in the fall is one thing, but to keep that good which is made in early summer is quite another. The best and richest Pennsylvania butter is made in May, June, and July, when the cows' milk is strong, and before the flies trouble them too much. The best of butter may easily be kept good till April; and this is the way to do it:—

First:—It must be good butter when made; all the buttermilk must be worked out, and in doing this keep it out of water—don't have any water come in contact with it. Butter that is washed in working, as it is termed, if good, would be much better if it had not been washed. Salt to suit the taste of those who are to eat it; half an ounce of salt to a pound of butter is about right; keep out saltpetre, sugar, and all other curative ingredients; it will keep better without them, and perhaps, too, without salt, but will not be so palatable. Do up the butter after each churning in neat, round rolls of two or three pounds each; cover each roll with a clean muslin cloth, large enough to go round it twice or more, so that it will be completely enveloped, and sink it in a strong brine as strong as the best salt will make it. Stone vessels are the best, and each roll, as it is put in, may be sunk by placing a clean stone on it.

Continue to add more rolls until the vessel is full, always keeping the whole completely covered with brine, and to insure strength add more salt when full. Keep it in the cellar or spring house, and see if it is not worth in winter or spring 100 per cent. more than any winter-made butter. In this manner a supply of choice butter may be kept perfectly safe. But, mark, the butter must be good—well made by one who understands how to do it, must be well worked, and should by all means be wrapped up, and sunk under the brine, the same day that it is churned, not kept lying around for two or three days after churning.

A good spring, with the water at 56 degrees, is indispensable to make the best butter in the summer months, and then it must be churned slowly, that it may come solid. Bradley's Atmospheric Dasher Attachment is superb, making the old barrel churns complete atmospheric churns, with half the revolutions breaking the butter just as soon; then, in warm weather it is solid and firm, and no trouble to wash out the milk.—*Prairie Farmer.*

Accounts with the Cows.

The author of Ogden Farm Papers in the *American Agriculturist* says:—We are just commencing to keep a record of the weight of milk given every morning and evening by each cow. A printed blank for each week is tacked against the wall, and a lead-pencil hangs near it. As each cow is milked, the pail is hung on an ordinary spring scale. The pails being of uniform weight, it is easy to make the record sufficiently accurate for practical purposes. At the end of each week the total yield for each cow is footed up, and divided by seven for the daily average. The total weekly yield of the whole herd is also recorded. The utility of such a record, especially if continued for a series of years, will be great. It will show: 1. The performance of each animal in her different conditions, and especially the degree in which she holds to her milk towards calving time. 2. The relation that the progeny bears in its milking qualities to its dam. 3. The milk producing quality of the progeny of certain bulls. 4. The effect of different kinds of food, and of different systems of feeding on the production of milk. 5. By comparing the weekly yield of milk with the weekly production of butter, the effect of feeding can be determined in regard to this latter.

The practical results of the knowledge thus obtained will be valuable. We shall know which animals to sell and which to keep; which bulls to breed from; which families to depend on for the final herd, and what methods of feeding it is best to pursue in winter and in summer—this will be especially valuable as showing the relative advantages of soiling and steaming, as compared with dry feeding and pasturing, and the relative value of corn meal, wheat, bran, etc.

How to Treat Kicking Cows.—A friend told us the other day of a method of treatment that he had found successful in curing cows of the habit of kicking while being milked. It is as follows:—As the cow stands in the stancheons, he puts a bull-ring in her nose, throws the rope attached to the ring over a beam or girt above the head of the cow, and drawing her head as high as possible without raising her feet from the floor, makes fast the end of the rope. The cow cannot kick while standing in this strained position, and the milking process is then conducted gently and rapidly. As soon as she learns that she has nothing to fear from the milker, but everything to fear from the ring—and this knowledge she is said to acquire rapidly—she is cured of her disagreeable habit. A young heifer may often be thus cured by a single application.

Grafton Cheese Manufacturing Company.—A company is about being formed for the manufacture of cheese in the vicinity of Grafton. The committee, appointed for that purpose by a public meeting, have secured a most favourable site, about one mile west of the village. Nearly all the required capital is already subscribed, and the buildings, upon quite an extensive scale, will be proceeded with at once, to have everything in complete readiness for business next spring.

Poultry Yard.

Physiology of Eggs.

Every fowl has two small organs near the extremity of the body, called the ovaria. It is filled with elastic tissue, and feels under the finger like sponge. The eggs are started here, and those which will mature a year, or two or three years hence, are in embryo. One is forced up and seized by the stroma, which is seventeen inches long, and passed rapidly through. When the egg leaves the ovary it consists of yolk only, but in its passage through that short canal, the yolk is surrounded by enough albumen to perfect the chick. The white of the egg has in it all that nature requires for making bones, muscles, blood-vessels, connecting tissue, skin and feathers. Just before the egg leaves the body, this canal has the power of secreting lime for the shell. This shows how valuable the egg is as nutriment, and it also shows what demands are made for rich food by a hen that lays an egg daily. Besides what she requires for her sustenance, she is called upon to secrete the material for the body of an entire chick, and also retains for the little creature sufficient to last many hours after it leaves the shell. It shows also that a hen cannot make albumen so rapidly, except out of albuminous food, such as wheat, meat, and small animals. It is not true that there is a certain number of eggs, and that, this number exhausted, no more can be expected; but it is true that the secretions lessen as old age comes on, and latterly the hen fails to have sufficient force to carry forward the process. The practical bearing of this is, that we must see that the fowl is always well kept. The way to have good laying pullets is to quicken the circulation and strengthen the system by liberal nutriment.—*Ex.*

Vulture Hock.—A correspondent wishes to be informed as to what constitutes this defect. The vulture hock is the projection of feathers behind the knee, and inclining towards the ground. The feathers of a fowl's leg usually should be close around the knee, and the leg clean below it, like that of a boy wearing Knickerbockers. In a few breeds, such as the Booted Bantams and Ptarmigans, this kind of feathering is necessary, but in Cochins and Brahmas it is considered a serious defect.

Loss of Feathers.—This is a complaint to which fowls confined in close yards or houses are liable, and is best combated by scrupulous attention to cleanliness, and by giving with dry food a supply of vegetables and insects, and other animal substances. Tegetmeier recommends five grains of Plummer's pill, given occasionally at intervals of two or three days. But, as this composition contains calomel, we doubt its propriety or efficacy for poultry. A little sulphur might be useful, but diet and cleanliness are the chief points in the treatment.

Entomology.

The Cattle Fly.

From many parts of the country, as well as from this neighbourhood, we have received complaints of the grievous injuries inflicted upon cattle by the attacks of a small fly. Many cases also have come under our own notice. In some localities, the attacks of this creature have been so numerous and persistent, and the irritation produced by them so severe, that the farmers have concluded that their cattle were afflicted by some malignant disease of a novel and destructive character. Their alarm, we trust, has been to some extent allayed by the letters of Mr. Smith and others, that have already appeared in the Daily Globe. We now hope that they will relinquish their fears and set to work at once to employ the means recommended for the alleviation of their stock, and the warding off of the enemy.

The fly that has been doing all the mischief is called the *Stomoxys calcitrans*—the former name meaning "sharp-mouthed," the latter "kicking," applied to the insect from the effect its bite produces upon cattle. It is smaller, but resembles considerably the common house-fly (*Musca domestica*), and belongs to the same family (*Muscidæ*) of two-winged insects. Upon close examination it will be found to differ from the house-fly in the form of its proboscis, which is very long and slender, and projects horizontally from the head. It lays its eggs in the dung of stables and barn-yards, upon which its maggots feed. It closely resembles the house-fly in its transformations. The usual time of appearance of this insect is the end of August and early part of September, but this year, owing probably to the unusual heat of May and June, it has been developed earlier, and become infinitely more numerous than in ordinary seasons. The same excessive development has taken place in the house-flies this year, and is the subject of bitter complaint all over the Province. The cattle fly often comes into houses in rainy weather, and does not scruple to attack human beings, inflicting a sharp wound, and usually drawing blood. We have often been tormented by them, and observed the structure of their proboscis and their mode of procedure. The house-fly worries by creeping over the skin and putting down its trunk-like sucker to draw up the moisture; but the cattle-fly thrusts its sharp-pointed proboscis into the flesh, and proceeds to imbibe the blood of its victim, causing him to start, and possibly execrate the molester. The effect produced upon the legs of cattle by the combined attacks of hundreds or thousands of these creatures can readily be imagined by any one who has experienced the bite of a single specimen; the wonder is that the poor creatures display the amount of patience that they do.

The only remedies that we know of for warding off these pestilent creatures are the following: 1. Wash all the parts liable to be attacked with an infusion or "tea," made of the common smartweed (*Polygonum hydropiper and P. acre*) which grows in waste places all over the country, especially in spots which have been covered with water in spring and fall, but are dry in summer. 2. Wash the animal with a solution of carbolic acid soap. These are both useful preventives. For treatment of cattle already affected, we must refer the reader to the veterinary department, as that part of the subject does not come within the scope of practical entomology.

All our readers have, no doubt, heard, if not read, about the "Tsetze fly," which is so destructive to cattle in Central Africa. Its ravages have been vividly described by Dr. Livingstone in his "Missionary Travels and Researches in South Africa." This formidable insect (*Glossina morsitans*) belongs to the same family (*Muscidæ*) as our insect, but it is of a larger size, and of a much more dangerous character. It stings mortally the ox, horse, sheep, and dog; but is not dangerous to man, to any wild animals, or to the pig, mule, ass, or goat. "It darts from the top of a bush as quick as an arrow on the object it wishes to attack," writes a French traveller. "This sucker of blood secretes in a gland, placed at the base of its trunk, so subtle a poison that three or four flies are sufficient to kill an ox." Thank God, we have nothing so terrible in North America!

Black Currant Worm.

Our Black Currant trees were desperately attacked this summer by the Measuring Caterpillar, a yellow variety somewhat different to that of last year. The eggs are laid by a dun, yellow-coloured butterfly, or rather moth; and two weeks since there were scarcely any leaves remaining on the whole row of trees. We had tried hellebore, tobacco, lime, whitewash, alkali, soap suds, hot water, and indeed almost everything we could think of—amongst the rest, coal oil mixed with water, and during the application kept in constant agitation, so that only a small portion was very sparsely distributed with the water over the bushes. All would not do; nothing killed these pests. At last, in desperation, we tried corrosive sublimate, one ounce dissolved in four pails of water—a most deadly poison—with which we watered the trees freely, believing nothing with life could withstand this treatment. But the worms "increased and multiplied," until absolutely starved away for want of food. The curious fact connected with the treatment is, that the currant crop does not seem at all injured, there being now more ripe currants and currants yet to ripen than we ever had before, although somewhat late, and a fresh crop of leaves again graces the trees; very young, to be sure, but bidding fair to be as great as ever. The worst is to come; now that we have a crop and the worms are all gone, we have used so many poisonous articles as to make us fear to eat the currants. Probably the wet weather may have washed away the corrosive sublimate; but we do not know this, and consequently are afraid to make any pies or preserves with them.

It is, however, a curious fact that the denuding the bushes of their leaves should not have ruined the crop of fruit. It certainly somewhat retarded the ripening, but does not seem to have injured the quantity. Last year our red currants were stripped in the same way, and great loss was sustained to the crop, and I am aware of many who lost trees and all by the worms. Whether we ultimately killed the worms or not I do not know, but believe not, as no application that we could subject them to seemed to hurt them in the least.

C.

About CaterpiHars.

To the Editor.

Sir,—Trees generally have had a large assortment of caterpillars this year. Elms were considerably affected early in the season, and just now I see some very large caterpillars marching in solid phalanx over the white willows. Apple trees have furnished a great variety. The ordinary Tent Caterpillar was numerously represented in May. Now we have the Fall Web-worm, also using a tent, and two other kinds which march in a body. One of these was described in the Canada Farmer last year (page 328), from specimens which I furnished. The other resembles it in its habits, and I will send a specimen with this communication. But in addition to the above we have some queer customers who work singly.

1st. A large green worm resembling the much dreaded Tomato-worm, but devoid of *that horn*. It is rather prepossessing in appearance, having two rows of orange protuberances on the back; the front ones marked with dark spines, and side rows of fine blue spines. I kept one on a small crab-apple tree, but it suddenly disappeared. 2nd. A bristly caterpillar (as per specimen forwarded) having an imitation of four feet extending laterally, and composed of black bristles. The body is mostly covered with yellow bristles, while both sides and four spots on the back are black. 3rd. An extraordinary-looking smooth green worm, with a yellow ring about its stout neck. Its body tapers from head to tail—and such a head! It resembles the head of a codfish, or some other fish; even the eyes are there. It has a flesh-coloured-extension-style of snout, and when angry, which is not seldom, it projects two horns, which give forth a perfume just like that of the Celery-worm. I will send you

the only specimen I ever saw; notwithstanding his uneven temper I hate to part with him.

I should be glad to know more of these solitary kinds of leaf eaters.

E. R. M.

Halloway, Aug. 9th, 1870.

NOTE BY EDITOR.—The caterpillars "marching in solid phalanx over the white willows" are, no doubt, the large black spiny larvæ of the Camberwell Beauty Butterfly (*Vanessa antiopa*, Linn.), which we have figured in the August number of the CANADA FARMER. The large green worm, one of the "queer customers who work singly," is the larva of the Cecropia Emperor-moth, referred to several times lately. It appears to be very common this year; we recently observed a small tree at Collingwood with about twenty specimens upon it, which the owner killed with coal oil. The "bristly caterpillar" belongs to the family of "Woolly Bears" (*Arctiadæ*), so called from the shaggy appearance of the caterpillars; some species of this family are very destructive, as, for instance, the Fall Web-worm (*H. Textor*), while others are rare and very beautiful, both in their larval and winged states. We are not familiar with the specimen before us, and therefore cannot give its specific name. The "extraordinary-looking smooth green worm" is the larva of one of our handsomest butterflies—the Tiger Swallow-tail (*Papilio turnus*, Linn.). The strange mimickry of a head presented by the anterior segments of this caterpillar, and one or two others of the same genus, is very remarkable; it is probably intended by a wise Creator to render their appearance formidable and save them from the attacks of enemies. This species feeds upon the leaves of apple and cherry trees, but is never sufficiently numerous to inflict much damage. When full-grown, towards the close of summer, it selects some secluded spot and turns into the chrysalis state, first attaching itself by the tail to some convenient object, and then supporting itself by a silken girth passed around its body. It remains in this state all winter, and appears as a large handsome yellow and black butterfly in the following [illegible]. All the caterpillars of the Swallow-tail butterflies (genus *Papilio*) possess the curious orange coloured tentacle shaped like a Y, and giving out a strong and rather disagreeable odour. The "celery-worm" referred to is the larva of the Black Swallow-tail (*Papilio asterias*, Fab.)

Entomological Queries and Replies.

EMPEROR MOTH CATERPILLAR.—A. R., Hagarville, Ont.—The large caterpillar found by your wife on the apple-tree is a specimen of the larva of the great Cecropia Emperor-moth; it is quite different from the Tomato-worm, and is not at all poisonous. You will find a picture of the moth and the cocoon formed by the caterpillar in the July number of the CANADA FARMER. The eggs so tightly fastened to the limb of your apple-tree do not belong at all to this insect, but were laid by a very much smaller moth; if allowed to remain on the tree they would hatch out early next spring, and produce a brood of the well-known Tent-caterpillars. You do well to burn all you can find.

IO-MOTH CATERPILLAR.—B., Mimico, Ont.—The beautiful, pale yellowish-green caterpillar, covered with tufts of branching spines, and with a red and white stripe for three-fourths of its length along each side of the body, found by you on a currant bush, is the larva of the handsome Io-moth (*Saturnia Io*, Fab., *Hypercheria varia*, Walk.). It is almost the only caterpillar we know of in this country that can in any way injure the human person; if handled incautiously, its prickly spines will sting the more tender parts of the body—as, for, instance, the back of the hand—like a nettle. The moth is of a very beautiful bright-yellow colour, and has its hind wings adorned with a handsome eye-like spot resembling that on peacocks' feathers; it is thus somewhat similar to the Polyphemus Emperor-moth, figured in the July number of the CANADA FARMER, but is much smaller, its wings only expanding to a width of about three inches. The caterpillar feeds on a great variety of trees and plants; viz. willow, elm, balsam, poplar, dogwood, assafras, locust, cherry, Indian corn, clover, hop, and—according to you—currant also.

WALKING-STICK INSECT.—W. Woodman, Leaskdale, Ont.—The strangely-shaped specimen that you captured on the outside of your window-sash is a female Walking-stick Insect (*Diapheromera femorata*, Say). We were glad to receive the eggs that you enclosed, being two out of five that the creature laid the first night of its capture; we have had specimens of all sizes and ages of the insect, but never before saw its eggs. The male differs from the female in being of a greenish and not brownish colour, and in being furnished at the extremity of the abdomen with a singularly shaped pair of claspers, instead of an ovipositor. The eggs are of a flattened oval shape, whitish on one edge, very dark brown on the sides and other edge, and with a black ring around the tip of one end which is of a paler colour. You will find some account of the creature in the last number of the WEEKLY GLOBE, and further remarks in the January number of the CANADA FARMER.

CRICKET AND HAIR-SNAKE.—G. G., Beachville, Ont., writes as follows:—"When crossing the parlor floor this evening I stepped on a cricket; at the moment my daughter was busy at the table securing some butterfly specimens in a case, and stooping down I lifted the cricket to prevent its being squashed on the carpet, and handing it to her I said 'There is something else for you to stick a pin into.' She took up the cricket, and on examining it said, 'Why, this cricket has a tail!' and almost in another instant she exclaimed 'Father, look at this!' On turning, I saw a snake-like production, which had just come from the cricket, wriggling on the table. Now, this may be a common enough production, but—in my ignorance, perhaps—it seems to me very curious and uncommon. I should, therefore, like to hear some scientific account of it. The product of the cricket has a mouth, and it measures eight inches in length; and what astonishes me most, perhaps, is how such a thing could pack itself away in the body of this small cricket."—The occurrence thus graphically described is certainly one of the curiosities of nature, though not altogether uncommon. The snake-like creature is one of the so-called Horse-hair Snakes, a species of parasitic worm (*Gordius*) about which we have said a good deal in these columns. A short account of the creature will be found in the July number of the CANADA FARMER. It is certainly a great marvel how eight inches of Gordius can be packed away in a small cricket, though, to be sure, the former approaches very nearly to the mathematical definition of a line, "length without breadth," and can coil itself up into a very small compass.

VARIOUS CATERPILLARS.—Subscriber, Toronto.—The large caterpillars, whose spines caused a prickly sensation when they came in contact with the fingers, are specimens of the larvæ of the Io Emperor Moth (*Saturnia Io*, Harris; *Hyperchiria varia*, Walker), the only Canadian caterpillars we know of that possess this urticating power. They feed upon a great number of plants, as we mentioned in a recent reply to "B, Mimico." The pretty green caterpillar with golden yellow and black oblique stripes along the sides, and a stiff projecting tail at the posterior end, is the larva of the Ash-coloured Sphinx (*S. cinerea*, Harris). It feeds upon the leaves of the lilac and privet, coming to its full growth about the close of the summer, when it goes down into the earth and forms its chryaalis, emerging as a large ash-coloured humming-bird moth during the following July. The caterpillar sent was not nearly full-grown; they sometimes attain to the length of nearly four inches. The tomato with the caterpillar inside, that you speak of having sent us, has failed to make its appearance; the insect was probably the Bell-worm (*Heliothis armigera*, Hubr.), which is very injurious to both corn and cotton in the United States, and also shows a great fondness for tomatoes.

CATERPILLARS DESTROYING CARROTS.—We have received from an anonymous subscriber several beautiful velvety-green caterpillars, ornamented with transverse bands of yellow and black spots; he complains that they are destroying his garden carrots, and desires to learn from us something about them. They are the larvæ of the handsome black Swallow-tail Butterfly (*Papilio asterias*, Fab.). These caterpillars feed upon a large number of both wild and cultivated species of umbelliferous plants. Harris enumerates the following:—Parsley, carrot, parsnip, celery, anise, dill, caraway, and fennel of our gardens, as well as on the conium, cicuta, sium and other native plants of the same natural family." They are not often so numerous as to be destructive, but when they are, the only remedy appears to be careful hand-picking.

COLORADO POTATO-BEETLE AT STRATFORD.—Our friend, Mr. N. H. Cowdry, of Stratford, Ont., has sent us a specimen of this beetle, which was found on a sidewalk in that town on the 23rd of July. He remark that "it has probably done no harm among the potatoes this year, as there have been no complaints as far as I have heard, and this is the first one that I have seen." We fancy that we shall hear complaints loud and deep from the potato-growers of Stratford next year, if the advanced guard of the Colorado army has already reached them; we trust they will keep a sharp look-out and destroy the invaders as fast as they make their appearance. It is astonishing how rapidly this pestilent insect is advancing eastward.

SPIDER AND WASP.—F., of Fergus, Ont., writes as follows:—"I send you what is a stranger to me, a white and pink spider which I captured two days ago with the wasp dead in its arms, clinging to the sweet-pea. If you notice the colours, you will observe, that, to a shade almost, those of the spider and sweet-pea are identical. The spider was hard to kill, as it fell into the phial of alcohol and lived two or three minutes. The likenesses of the large moths in the last number of the CANADA FARMER are capital." We have several times observed this pretty species of spider about flowers, though not always the sweet-pea; its colours are probably designed to render it inconspicuous when amongst flowers, both to its enemies and to the objects of its attack. The wasp, a large "Yellow-jacket," much bigger than the spider, had evidently "canght a Tartar," and found his wily antagonist more than a match for him.

CATERPILLARS.—We have received by mail a box of caterpillars, bearing the Kincardine post-mark, but with no name attached to it. It would have been much more satisfactory had the sender afforded us a little information as to his desires regarding the specimens; however, we shall take it for granted that he wants them to be identified for him.—(1). The two large green caterpillars, each furnished with a curved reddish-coloured tail, and ornamented on each side with seven oblique lilac stripes, edged with white below, are larvæ of the Plum Sphinx (*S. drupiferarum*, Smith & Abbott). They pass the winter in the pupa state under ground, and emerge as large ashen-coloured "humming-bird" moths in the following summer. One of these caterpillars has been attacked by some parasitic ichneumon, and appears decidedly unhappy; his days are evidently numbered.—(2). The small hairy caterpillars are specimens of the Fall Web-worm (*Hyphantria textor*, Harris), which lives in communities protected by large web-covered nests on apple, plum, cherry, ash, willow, and various other trees. It must not be confounded with the Tent Caterpillars (*Clisiocampa*), which appear in early spring and turn into rusty-brown coloured moths; but it appears about midsummer and remains upon the trees till late in autumn, coming out the following year as a pretty snow-white moth, free from any markings on the wings, but with its fore-legs yellow, and feet alternated with black and white.

WALKING-STICK INSECT.—W. Coleman, Vroomantown, Ont.—The curious thin-bodied, long-legged insect, much resembling a stick with legs to it, that you have sent to us, is a specimen of what are commonly called Walking-stick Insects or Spectres (*Diapheromera femorata*, Say). Like the so-called Hair-snake (*Gordius*) that ignorant and superstitious people believe to be derived in nine days from a horse-hair dropped in water, this singularly shaped creature has been the subject of many wondrous stories. One, for instance, relates how a dead stick sprouted and put forth legs, and presently walked away before the affrighted gaze of the historian, who thereupon believed that some dire event was about to befall the human race! This odd creature is not uncommon, but is seldom observed by unpractised eyes, owing to its wonderful resemblance to a stick; it feeds upon young shoots and tender leaves, but is never numerous enough to cause appreciable damage.

BEE HAWK-MOTH.—John Carroll, Oakville, Ont.—The moth you sent us is a specimen of what is sometimes called the Bee Hawk-moth, or Clear-wing (*Sesia diffinis*, Boisd.); the former name is given to it from its resemblance, when hovering over flowers in the hot sunshine, to a Humble-bee, and the latter from the transparency of its wings. It belongs to the Humming-bird or Hawk-moth family (*Sphingidæ*), most of the members of which appear at twilight, poising themselves on their rapidly vibrating wings over flowers, and extracting the sweet juices with their long flexible tongues. The caterpillars of this family are furnished with a stiff, horn-like tail, the supposed sting of the innocent, but much blamed Tomato-worm.

THOUSAND-LEGGED WORM.—The Thousand-legged Worm or Millipede (*Iulus*) recently left at our office is not a true insect, but belongs to the Myriapods. Its body is of a dark chestnut colour, about three inches long, cylindrical in shape, and with an immense number of short legs; it crawls with moderate rapidity, and coils itself up on its side when at rest. It lives under old logs, where we have often found specimens when searching for insects, and feeds upon decaying vegetable matter. By many it is called a Centipede, and therefore thought to be poisonous like the creature of that name in tropical countries, but it is very different in reality, and possesses no noxious qualities whatever.

STRANGE CATERPILLAR.—Daniel Reynolds.—The beautiful green caterpillar, with the strange eye-like spot, found by you on a dish of apples, is the larva of the handsome Tiger-Swallow-tail Butterfly (*Papilio turnus*, Linn.). See our remarks on the communication of E. R. M., headed "About Caterpillars," for further particulars respecting this creature.

The Apple Curculio.

(*Anthonomus quadrigibbus*, Say.)

We have received from J. H. H., Millbrook, Ont., a specimen of the Apple Curculio—an insect that has not yet been much observed in Canada, though well known to entomologists in the western parts of Ontario. Our correspondent writes that "it had done a good deal of damage by eating a considerable portion of the surface of several apples. I could only (he adds) find a single specimen, though the appearance of a number of apple showed that there were more."

The accompanying illustration gives an excellent representation of the Apple Curculio, considerably magnified, the natural size

being shown by the small figure *a*. *b* represents a side view, and *c* a back view of the beetle.

This insect is about the same size as the only too-familiar Plum Curculio (*Conotrachelus nenuphar*, Herbst.), but may be readily distinguished from it by its much longer and more slender snout; its colour, which is dull brown, shading into rusty red behind; and the four conspicuous humps on the wing-covers behind the middle, which are brownish-red, and not shining black, as in the case of the Plum Curculio. Its original fruit appears to be the fruit of the hawthorn and other similar indigenous trees, but of late years it has been found to attack the apple, often to a very injurious extent. The late Mr. Walsh relates in the *Practical Entomologist* that, in 1864, fully one-half of the fruit of some trees at Beverly, Illinois, had been punctured by it, hardly an apple on the lower limbs escaping its attacks, and many having eight or ten holes in them. It makes round and not crescent-shaped holes in the fruit, most of them apparently for the purpose of eating, as but a small proportion have been observed to contain eggs or larvæ. The only known remedy for its attacks is vigorous and continued "jarring."

Apiary.

Feeding Bees and Strengthening Stocks.

Feeding or strengthening weak stocks by giving cards of honey from strong ones is generally delayed too long. The bee-keeper will find it a great saving of syrup or honey, to feed early, as the bees will deposit far more of what they take up if fed just at the close or winding up of the honey harvest. In all localities where there is but little fall pasturage it would be well to feed in August, or at the latest by the first of September.

At this season most of the feed given them will be deposited in the cells, and capped over the same as the honey brought in from the field, which prevents its becoming sour and unfit for winter use. And if stocks are to be strengthened, it disturbs the bees far less to do so while the weather is warm, and the bees will not consume so much of what is given them if it is given early, when they are gathering a little. Feeding or giving cards also stimulates to greater industry, and seems to encourage labour in the field, when given early, before all the flowers are gone.

Let bee-keepers try it, and they will not feed late afterwards. As a rule, it does not pay to keep stocks that require much feeding; still, many stocks with a very little early feeding would become good ones, and in such instances it pays to feed.

J. H. THOMAS.

Brooklin, Ont.

The Honey Season of 1870.

Now that the honey harvest is over, or nearly so, for this season, it may be well to compare notes with last year. For several years past we have not had what might be considered a first-rate season for bees, but that of last year proved to be the worst we have had for years. The season was wet and cold, bees could not work well, and the honey gathered was of an inferior quality.

At the time bees were put into winter quarters, the best judges supposed that the stocks had sufficient stores for winter use, but it appears that the hives were weighted with bee-bread to an unusual degree, and the honey was poor. The consequence was that there was a fearful loss of bees throughout the country, many even losing their entire stock, while others lost heavily. Hence this season opened with fully one-half less of bees in the country than last fall. The season, however, though a little dry, has been one of the best for many years, so much so that the loss of last winter is nearly if not quite made up, and far more honey has been taken than for years past, while the increase in stocks is all that can be desired.

The honey gathered is of an excellent quality, and stocks generally are well supplied with winter stores. O FitzWilkins writes that from one stock in a Thomas hive he took four boxes of twenty pounds each, making eighty pounds of pure virgin honey, and 142 pounds from the body of the same hive, with the honey extractor, making altogether a yield of 222 pounds of honey from one stock, which at 20 cents per pound would amount to $44 40. Mr. John McLatchie, of New Edinburgh, writes that in the spring he commenced with 57 stocks—50 good and 7 weak or poor ones. He increased to 96, and took in boxes a little over 2,000 pounds in virgin honey, and 500 pounds with the honey extractor, making altogether an increase of 39 stocks and 2,500 pounds of honey from 57 stocks, including the weak ones.

The prospect is also that bees will go into winter quarters more than usually well stored with good honey, and if all be well we may expect them to come out in fine condition in spring.

J. H. THOMAS.

Brooklin, Ont.

NOTE.—Since writing the above we received a letter from Mr. McLatchie, saying that on the 17th August 46 stocks of bees, about 2,000 pounds of honey, and all his surveying instruments and clothing, were consumed by fire.

Ventilation of Stocks in Winter.

After all that has been written relative to the ventilation of hives in winter, the right principle is little understood. It is true that bees winter better when the moisture is carried off by upward ventilation, provided the heat is retained; but it is absolutely as necessary to retain the heat generated by the bees in the hive as to get rid of the moisture, if the former object is not even more imperative. Evidently, then, proper ventilation should allow the moisture to escape while the heat is retained. This may be done in the following manner. Cover all upward ventilating passages or openings with some warm material that will absorb the moisture, but retain heat. Thick flannel or woollen cloth, an old bag, or quilts made for the purpose, will answer. Hence, if the honey-boards of the Thomas hive are removed entirely, and a frame covered with wire cloth or strong linen put on instead, and over this some warm material, the moisture would entirely escape, leaving the bees and combs dry, while all the heat would be retained.

J. H. THOMAS.

Brooklin, Ont.

An army of bees are said to have swarmed into a church in Gloucester, Mass., one Sunday, during divine service, but retreated when the sexton shook the contribution box at them.

Bee Culture—Controlling Fertilization—Hungarian Process.

Mr. Semlitsch, an experienced German apiarian, communicates to the *Bienenzeitung* a method of controlling the fertilization of queen bees with selected drones, which is merely a modification of the plan already made public, but which will interest apiarians, and may suggest some useful practical hints. The process described was invented by Mr. Dax, of Duns, in Hungary, and is thus described by Mr. Semlitsch:—

"For our purpose we need, first of all, a common cylindrical wire gauze queen cage, fastened securely to the middle of a piece of board ¼ inch thick, and having a ⅜ inch hole through its centre. This board must be sufficiently large to cover the hole in the top of the hive. A second similar board serves to have a queen cell attached to its under side with melted wax, and is laid on the first mentioned board, with the queen cell passing through the ⅜ inch hole—thus closing the queen cage. Next we need a tin plate six or seven inches square perforated with numerous small holes, so small that a worker bee cannot pass through. And finally, we need a four-sided case of wire gauze or a glass cylinder, six inches wide and six or seven inches high, open at top and bottom, and having within, on one side, three or four inches from the bottom, a wooden peg or spear on which a small piece of honey comb may be suspended. These are all the requisite materials.

"When we are having queens reared, it is important that we should note the day on which the cells are sealed. On the second day thereafter cut out a queen cell, attach it by means of melted wax to the under side of the second board above described. Then, inverting the board, pass the cell through the ⅜ inch hole of the first mentioned board, into the queen cage, so placing the board that the cell shall be freely suspended in the cage, with room all around and below, for the young queen to emerge when mature. With the second board then placed on the first, the queen cage is perfectly closed. Now open the hole in the top of the hive, and place the board on it, with the attached queen cage passing down into the hive as far as the board to which it is fastened will permit. Close all crevices tightly, and cover the whole with a piece of blanket doubled and securely fastened. By lifting the blanket and raising the upper board to which the queen cell is attached we may at any time ascertain whether the queen has emerged or not. On finding that she has left the cell, we wait four or five days longer, or more precisely, from after the third till the first fine, warm and favourable day that occurs, such as young queens themselves select for their bridal excursions. On such a day, we lift out the queen cage with all its adhering bees, cover the hole in the top of the hive with the perforated tin plate, and set the wire gauze cage or glass cylinder on it; thrust into it the adhering bees from the queen cage, liberate the queen, let her pass down among the bees, and cover the top of the case or cylinder. There ought to be somewhat more than a hundred bees in the cluster. Should there not be so many, draw back the tin plate gently and let an additional number of workers pass up. Now suspend a piece of honey comb on the peg or spear, cover the case or cylinder, and place it in a dark chamber. At any time between eleven o'clock in the forenoon and three o'clock in the afternoon, a selected drone may be introduced, light partially admitted, and fertilization will soon follow. Should it not take place on the first day, the experiment must be repeated on the next, when it is almost sure to occur. Mr. Dax assures me that he had frequently used the process, and only on two or three occasions had he found it necessary to introduce a second drone, and was then invariably successful. 'Make the trial,' said he, 'it will not fail.'

"Apart from the undoubted credibility of Mr. Dax, other strong reasons lead us to presume that a successful result would follow a properly made experiment. Why does not fertilization take place within the hive itself? Evidently because in the crowded condition of a colony it could not be effected without interference, leading to commotion which might endanger the life of the queen. This being so, natural instinct has provided that, for this purpose, the queen shall leave her hive. Even should the bee-keeper undertake to interpose in the ordinary manner, by catching, confining and removing the queen, she would still be filled with alarm, and all her efforts would be directed to effect her escape and return to her hive—excitement and anxiety dispelling every other passion or natural impulse. Whether a queen thus removed be liberated in a roomy chamber and permitted to fly among workers and selected drones, or allowed to fly in the open air, restrained only by a silken string, the desired result will rarely be attained. But by the method employed by Mr. Dax, the queen becomes neither alarmed nor excited, for she is born in a state of confinement; and when permitted to mingle with a limited number of workers, she feels herself free and companionable, yielding readily to her natural impulse to provide for the growth of the small colony. If now a mature drone be introduced, fertilization will almost certainly follow, because, from the small number of workers present, clustered too, for the most part on the inserted honey comb, no interference or disturbance need be apprehended. Such are the grounds which induce me confidently to expect a successful result.

"Next spring I shall prepare for the hives having a honey chamber in the top, a division board 1¼ inch thick, with a suitable centre hole, substituting it for the ordinary top division board, for the purpose of experiment. If I should then also separate the honey chamber by means of glazed division frame, I may possibly be able to dispense with the wire gauze case or glass cylinder. But in such case the tin plate must have precisely the length of the common top division boards, and take the place of the division board with the central hole."

The above process, it will be seen, is very similar to the method already described in this journal. We have experimented with one queen, and succeeded in getting her artificially impregnated.

ED.

Profits of Bee-Keeping.

To the Editor.

SIR,—I commenced last spring with one hive of Italian bees from the stock of J. H. Thomas, Brooklin, Ont., in one of his patent hives.

I have now ten splendid swarms, all of them being almost too full of bees to work with profit, besides a good deal of surplus honey. I had another swarm last week, but returned it to the hive, as the season is so far advanced.

All the bees in this locality have done very well this season, but none so well as mine; and the only reason is that mine are Italians, while the others are the common black bees. Does it not pay to keep Italian bees?

JAMES LOCKIE.

Listowel, Aug. 2nd, 1870.

Bees should have a liberal allowance of air during all extremely hot weather, and if the stocks are strong the entrance blocks may be entirely removed.—LANGSTROTH.

All the choicest spare honey should be removed from the hives, before the delicate whiteness of the combs becomes soiled by the travel of the bees, or the purity of the honey is impaired by an inferior article gathered later in the season.—LANGSTROTH.

It would appear from the following extract from Purchas that bees have been from time immemorial in favour of the present fashion of cropping the hair. This quaint writer observes:—"Bees are much offended with long hair on head or face. Let such, therefore, as must be often among them, wear short hair, or be well covered, on peril of stinging."

HONEY FROM LINDEN.—Bees are doing finely in this locality. The present prospects indicate a grand yield of surplus at the end of the harvest. The weather is fine and honey abundant. The Linden is in full bloom at this date, being some twelve days in advance of last year. To give the readers of the *Journal* some idea, I have taken notes of the following stands, four in number:—Weight of each in the morning, 66, 74, 78, 70 pounds; in the evening, same day, standing thus, 85, 71, 72, 76 pounds, making the sum total twenty-six pounds in one day. These were not No. 1 full colonies, all having been swarmed, or brood taken from. It would not be too great a stretch of the imagination to say that good colonies can double the above figures. Is this not enough to stimulate the cultivation of this favourite tree? Already I see a movement in that direction.—*Cor. American Bee Journal.*

Correspondence.

Crops—Irrigation.

To the Editor.

SIR,—At this date we are still busy harvesting hay. Fall grain and barley are nearly all housed and safe. Hay in this vicinity is rather light, especially clover, a great deal of which was winter-killed or ice-smothered, so that our main reliance is the surplus crop of last season, and the hardier varieties of grasses that survived. Timothy is very good in some localities, especially near the margin of creeks or rivers, made rich and moist by the spring inundations. The protracted drought of the spring affected the hay and barley materially. "Store is no sore," and those who were wise enough to keep their hay will profit thereby.

Barley does not yield as largely as last season; it is short, and ripened very unevenly, some being quite green while the rest around was quite ripe; this is especially the case on clayey soils. Barley needs generous culture. Farmers are too anxious about the quantity sown, and not careful enough about the quality. These heavy clay soils need a great deal of moisture and stirring to render them fit for spring crops. It would be better and surer on such soils to raise fall grain, which would receive all the benefit of fall, winter, and spring moisture, and would become rooted so strongly that the drought would have little effect upon it.

Very little fall grain has been grown in this township this year. Those who have held to fall wheat-growing are well repaid, both in yield and quality. The Diehl and Treadwell varieties especially have done well. We should grow more. Oats are an abundant crop. Spring wheat promises well. Peas are very good and well podded.

The subject of irrigation has engaged my mind of late. Can we not to some extent mitigate the severity of our periodical droughts by some artificial means? 1st. By securing the water that comes down our hill-sides and through our fields, and forming reservoirs from which it might be dispensed in time of need to the thirsty ground, through channels or pipes. 2nd. By using waggons or carts similar to water carts, with broad tires, and otherwise adapted to the purpose. 3rd. By the use of steam power and hose, one of which might serve for two or three concessions. 4th. By applying such manures to the soil as absorb moisture, and ploughing under green crops. 5th. Diverting the channels of creeks, and making them spread over a large area of land. In Eastern lands they seem to appreciate the gifts of inundations better than we. True, manual labour is cheaper; but here, with all the aids of machinery, much might be done to economize the water so lavishly bestowed upon us. Would not hydraulic rams be of service in this respect? I would like to hear more on this subject.

JOHN S. BOUTILLIER.

Sidney, Aug. 9, 1870.

The Potato Beetle.

To the Editor.

SIR,—You seem to be desirous of having the opinions of those who have suffered from the Colorado potato beetle.

I have grown about eight acres of potatoes this year—six acres of Garnet Chilis and two of Early Molters, a potato much grown about London, and in productiveness, earliness, and flavour, far surpassing the much vaunted Early Rose.

The beetle settled upon the Molters first about the second week in June, and whilst the tops of this potato were green, no beetles touched the Chilis, but when the Molters were exhausted they attacked the Chilis. I do not intend to say anything about the beetle that will encroach on the work of the entomologist: but I think that as yet there has been no practical mode of dealing with these pests made known to us. I look upon all the suggestions as to the mode of poisoning them as utterly useless, when potatoes are grown on a tolerably large acreage. In a small garden patch they may be sprinkled with hellebore, or shaken off and trodden on, or troubled with Paris green, but not when they are grown by the acre. The cost of doing any one of these things would swallow the potatoes, for they would require sprinkling every other day. This pest is not a caterpillar only; it has wings, and the beetles are marching westward at a considerable rate. They are constantly recruited by fresh arrivals. If the main army is destroyed, the reserve takes its place, and the militia succeeds, and the *levy en masse* comes after the militia, so that such modes of destruction are altogether impracticable to the farmer, though the cottage gardener with children may succeed in effecting their destruction.

What, then, will succeed? In difficulties of this nature it is, after all, to the practical farmer that we must look for an effectual remedy. One summer's experience is only of small value, but I will tell you mine. My potatoes were planted the first week in April; they were well up by the first week in May. Having no frosts in this neighbourhood at that period of the year is, no doubt, an advantage. The result of early maturity is this—that the crop of Molters were too far advanced to be much damaged, notwithstanding the loss of the tops. The Chilis are not so good as in ordinary years, having lost the nourishment they should have received from the injury done to their tops, but they are far beyond the same potatoes grown by many of my neighbours, but not put into the ground until after mine were well up. The reason seems to me to be that the beetle in mine did not destroy the tops until after the potato was well advanced, but with my neighbours the potato was much younger, and therefore suffered more from loss of the tops. One mode, then, of cheating the beetle will be by getting the crop in early, and selecting those kinds of winter potato which mature early. Now, the Early Molter is one of these kinds—one of the earliest, and good as long as you can get it, that is, as good in the next spring as any other potato. The Chili, for a winter potato, is an exceedingly early kind, and keeps remarkably well.

I am, of course, presuming from this year's experience that this pest will not commence its devastations earlier in any other year than it has in this, which may or may not be correct. Then, as to early planting, those parts of the country where there are spring frosts may be supposed to be shut out of my remarks. I think not, however, and I should plant as early as I could get the ground ready for them, and as soon as the tops peep above ground I would cover very lightly either with the hoe or double mouldboard plough, and repeat as often as the tops appear, until all danger of frost has gone. I do that here, although there is little chance of frost. I have done it at the London Asylum farm this year to protect the young tops from frosts. I think these measures of planting early and covering over, and selecting the earliest maturing kinds, may give us good crops until this pest disappears, as all such pests do in a few years, from some cause or other which scientific men have not yet discovered. I would add frequent hoeing and scuffling between the rows, in order to worry those insects which, in one form of development or other, hide themselves in the earth.

HENRY FANDON, M.D.,
Malden Asylum.

Amherstburgh, Aug. 22, 1870.

Lucerne, Etc.

To the Editor.

SIR,—I should be glad if you or your readers would, from actual experience, give me information on the following questions:—

1. Can Lucerne or Saintfoin be depended on to stand the winter for several years?

2. Will autumn-sown tares live through the winter?

3. Can a hay crop of tares be got off in time to get buckwheat in?

4. Will clover hay chaffed and steamed keep young pigs in winter?

A SUBSCRIBER.

REPLY.—1. From a limited experience with Lucerne we believe it will endure the Canadian winter. Many years ago we saw this crop grown on sandy loam soil, and although negected in its culture there was an excellent yield the first year. It was sown about the first of May, 1832, and endured our winters, and yielded two cuttings each year for about five years. It was then destroyed to make room for a garden. The owner, a bricklayer, knew little of farming, and took no care of the young plants even the first year. It was sown broadcast with barley. Many of the stalks were four feet high, and several horses were fed during the summer from it.

2. It is very doubtful if the winter variety of tares will survive the severe cold of this climate.

3. If sown early, there would be plenty of time after the removal of the crop for one of buckwheat.

4. We should not expect that such feed alone would suffice for hogs. It is even doubtful if they would eat it, however well they may relish the fresh, young and green clover.

Mouldy Beans.

To the Editor.

SIR,—In examining to-day a bin containing beans which had been lying more than a foot in depth, I found that beneath the surface they had heated and become covered with a white mould which rubs off with the fingers, and were very musty also. They had not been stirred in the bin since winter.

Though half ashamed to confess ignorance with regard to the necessity of stirring such crops in warm weather, yet I deem it a duty to give my dear experience to my brother farmers, lest some of them lose through similar neglect.

Please mention: How can such beans be used to best advantage? Can they be fed with profit to store sheep, or to sheep for breeding; if so, how should they be prepared? Is it profitable to raise beans for feeding on clay soils?

THOMAS SHAW.

Woodburn, July 29th, 1870.

DOUBLE IMPREGNATION.—A correspondent from Troy asks "whether it is possible for a sow to breed from two boars at the same litter?" Such an occurrence is certainly possible, and is not inconsistent with physiological laws. Well authenticated cases of a parallel character have been recorded as having taken place among animals where such instances must be rare, and with some animals the case can hardly be considered exceptional.

CALF FEED.—In reply to the enquiries of T. N. Sylvan, respecting feeding grain to his calves, we would say that a mixture of grain feed, such as he proposes, is very serviceable for growing as well as fattening stock. For the sake of obtaining variety, which is very desirable in feeding, by keeping up the appetite and strengthening the digestive powers, it would be well to alternate the various grains, rather than mix them all together at one time. From four to six pounds of grain daily would be sufficient for the calves, but they must have, in addition, a fair allowance of hay or straw, chopped and steamed, if possible. A proportion of roots also will, besides preventing constipation, prove very useful in the absence of green food.

SUBSOIL PLOUGH.—J. Morley, of Thorold, and W. Walker, London, manufacture them.

WINTER BARLEY.—Can any of our readers give information of recent experience with winter barley in Ontario?

CANARY GRASS.—The specimen of grass sent for identification by J. Y., Springfield, is Canary Grass (*Phalaris canariensis*), a variety which furnishes the well-known canary seed.

WILD RASPBERRY PATCH.—If enclosed, there should be no difficulty in dealing with trespassers; but if unenclosed, the enforcement of the owner's legal right might cost more trouble than the fruit was worth.

SNAILS.—Mr. F. Fowler, of Haysville, asks or a remedy for snails in the garden, having tried a number of applications in vain.—Snails can not travel in chaff, and if this be spread in a circle around the plants an inch deep, they will be found in the chaff with it adhering to their bodies. Air-slaked lime, sprinkled on theplants when they are wet, with dew is useful.

ALSIKE CLOVER.—A subscriber from Mount Forest writes:—"Would it harm Alsike clover, that was sown last spring, where there is a large percentage of red clover that was seeded in with the dung the previous year, to cut it now? There is quite a heavy crop, and I think it would smother with the weight of snow in winter." A very heavy crop, such as you describe, mixed with some of last year's seeding, might be cut now without damage, though under ordinary circumstances it would be best to let it alone till next year.

GERMINATION OF WHITE CLOVER.—T. N. is puzzled about the spontaneous appearance of white clover in his meadow several years after the first seeding. White clover is very capricious, so to speak, in germination. When purposely seeded, it will sometimes not come up for several years, and may then make its appearance in patches. It also appears spontaneously in blue-grass and other pastures, and increases in some years with extraordinary profusion. Wherever it springs up the germs must, of course, have been already in the soil, or been mixed with the other seeds used in artificial seeding. It is a kind of seed that will remain dormant, without losing its vitality, for almost an indefinite period.

WHITEWASH.—"Cultivateur" asks, "What is the best mixture for a whitewash for outbuildings?" The following is a good receipt for the purpose:—Slake half a bushel of lime with boiling water, when thoroughly slaked, add more water, two pounds of sulphate of zinc and one of common salt. Colour can be obtained by the addition of three pounds of yellow ochre for a cream tint; for fawn colour add four pounds of umber, one pound Indian red, and one pound of lampblack; for stone colour, use four pounds of raw umber and two of lampblack, and for lead colour add lampblack only.

The New Cattle Disease.

The following reply from Mr. Atkin the Secretary of the North Middlesex Agricultural Society, to a letter of enquiry from Mr. Buckland, Secretary of the Bureau of Agriculture, may be taken as a sample of others on the same subject, all giving uniform testimony of the nature of the disease.

Mr. Atkinson says:—"At a meeting of Directors of the North Middlesex Ag. Society, held at Ailsa Craig on the 29th inst., your communication of the 22nd inst., relative to "Cattle Disease," was read, when it was unanimously concluded by the Board, then in session, that there is at present in this section of the province no appearance whatever of a cattle disease; and that the so-called "cattle disease," or "plague," is nothing more or less than a grievous annoyance caused to the cattle by unusual swarms of flies. These flies, in low and marshy places, so afflict a beast as to cause in a few instances considerable swelling in the legs.

The appliance of almost any simple embrocation will not only prove a cure, but a sure preventative against the flies."

Advertisements for the "Canada Farmer" must be sent in to the office of publication early, and in order to secure their insertion in the forthcoming number, must in no case be later than the 7th of the month.

The Canada Farmer.

TORONTO, CANADA, SEPT. 15, 1870.

Harvest and Weather Notes.

Though the threshing-machine is the true measure of our cereal crops, and estimates formed from standing grain or the harvest field are often erroneous, yet the time has now arrived when a tolerably correct opinion can be formed of the produce of the year.

The accounts that reach us from outside our own Province are of a very varied character, but not on the whole discouraging. In Great Britain, notwithstanding the long-continued and extreme drought, the most severe with which the country has been visited for a great number of years, the returns are far from unfavourable. A report published in the *Mark Lane Express* and other British journals states that the harvest weather has been remarkably fine, and the quality of the grain for the most part excellent. With regard to wheat, the yield on light soils has been below the average, but that on the heavier lands has turned out well, and of superior quality. The barley crop is said to be poor, and about twenty per cent. under average. Oats are set down as fifteen per cent. under average. Beans have proved a comparative failure. Peas will be up to the average. The potato crop is reported to be looking well and free from disease. Other root crops are also promising. Hay has suffered seriously, and cannot be other than very short, though in the north of England and Scotland a much better account is given of this staple fodder.

Very little can be said of the Continental harvest. From a large portion of Europe, war news absorb every other interest. The fields that had suffered from the drought are rendered yet more fruitless by the devastations of opposing hosts. In the countries not implicated in the terrible contest, the season has not been unfavourable.

The reports from the United States represent a falling off in the yield of wheat, fair crops of other grain, and an abundant yield of Indian corn.

Within our own borders, the character of the season affords abundant grounds for thankfulness. Though in some districts short crops and comparative failures are reported, yet for the most part the yield of all field produce will be good. In some localities, the heavy storms of wind and frequent showers have seriously damaged the wheat, but the harvest returns of the country, taken as a whole, will probably come nearly up to the average. Root crops everywhere look well. The prices of farm produce, there is every reason to believe, will be good. Hay will, no doubt, be dear, not only because the crop will be somewhat short and damaged, but there will probably be an extra demand for export.

The accounts from the sister Province of Quebec are less cheering. Vegetation has suffered severely from the protracted drought, and the amount of damage inflicted by the forest fires has added a serious element to the tale of losses. The generous aid of the more prosperous dwellers in Ontario will be required, and, no doubt, be cheerfully rendered, to relieve, in a measure, the sufferers from these accumulated disasters.

The character of the weather during the past month may be gathered from the following notes, taken from the records of the Toronto Observatory:—

The mean temperature of the month was 67° 07, being warmer than the average of the past 30 years, by 1° 07, and warmer than that of August, 1869, by 3° 43. The highest temperature was 84° on the first, and the lowest 40° on the 27th. The warmest day was the 8th, the mean temperature of which was 73° 1, and the coldest day the 26th, with a mean temperature of 54° 8. The amount of rain-fall was 3.422 inches, being slightly (0,407) above the average, but below that of the corresponding month of last year by 1.688 inches. Rain fell on fourteen days, and eight thunder-storms occurred in this neighbourhood. During the thunder-

storm on the 5th, .60 inches of rain fell in 15 minutes, and .86 inches in 45 minutes. The sky has been perfectly clear only on seven days, totally clouded on four days, and partially so on twenty days. The prevailing winds have been westerly, with some easterly, and very little from either north or south.

A Day's Labour.

The "labour question," as it is somewhat vaguely called, has of late given rise to much controversy and some questionable legislation. Among other matters to be decided, the term of a day's labour has been warmly discussed, and while the limitation to ten hours or even eight hours has each found advocates, not a few are opposed to any restriction in the case whatever, believing that perfect freedom should be permitted on all hands, and that thus a right adjustment will be best secured. Yet that such freedom has been abused, and always will be, has been clearly demonstrated by experience. In the case of young children, for instance, it has been found necessary to protect the helpless class against the greed and cruelty of those who ought to be their most humane and tender guardians. When labour also is overabundant, and employers have from this fact a tyrannical power, it may be necessary to interfere on behalf of the over-tasked working man. But in this country the preponderance is all on the other side, and the tyranny is felt to be exercised by the labourers rather than by the men who require their services. This is the case more particularly in the agricultural community, among whom the supply of labour is certainly much below the demand, and the legitimate profits of farming are thereby often very unreasonably reduced. The "hire of the labourer" too often in Canada swallows up a most disproportionate share of the income of the farm.

Let it not be supposed that we would justify excessive demands on the labourer's powers or time, or that we are advocates for anything like unremitted toil. We are firm believers in the benefit, nay the absolute necessity, of relaxation, rest, and a fair amount of thorough recreation. But there are peculiarites about the farmer's calling that render the rigid application of any fixed rules in respect to working hours, such as might be quite compatible with the requirements of a factory or a store, altogether impracticable on the farm. The season during which the farmer has to complete all the operations of husbandry is very short, and often precarious; seed-time and harvest especially are periods of unavoidable hurry, during which the loss of a single day, or even of a few hours, may seriously affect the crop. A few hours may suffice to complete the seeding of a field just before a threatening storm or accession of wet weather, which, while it puts a stop to further work, may be just what was required for giving the seed an early start, and securing for that particular crop most important advantages, such as immunity from insect damage, strength to resist early frosts, or a gain of weeks, perhaps, in the time of maturity. And again, during harvest there are occasions continually occurring when it is of the utmost consequence to push on the work of in-gathering and securing under shelter the produce of the field with all possible energy and despatch, and it now and then becomes necessary to use every minute of daylight, or even to prolong the day's labour under the benign aid of the traditional "harvest moon." Such extreme occasions are, of course, exceptional, but when they do occur they are imperative, and no farmer would consent to forego the advantage of the extra hours under an arbitrary regulation to "quit work" at a certain time. The loss of a valuable crop may result from a few lost hours.

Taking one day with another, moreover the farm labourer has his compensations for these extra hours of work. The man who is hired by the year can set against the long days of summer, the very short days and often interrupted work of winter; and he who is engaged especially for harvest receives extraordinary and often exorbitant wages, which certainly should cover a little additional demand on his exertions. Wet seasons and storms will also often break into the regular course of work, and make the day's labour lighter, and often in effect shorter, without any corresponding deduction in the high rate of remuneration received. The men most likely to rebel against these unavoidable extra tasks are not the regular farm labourers, who have been brought up in the country and know the exigencies of farm life, but the occasional "city hands" who have been tempted by harvest wages to "hire out in the country" during the busy season. Such men often give no end of trouble, and farmers should resolutely set their faces against their unreasonable stipulations. Better dispense with their services altogether, than submit to their dictation; their help is often dear at any price.

There is, of course, another side to this question; and while the peculiarities of farm work render some latitude necessary in the hours of labour, there must on every well ordered farm be a generally regular system of daily work, and there need not be any immoderate share of toil. There is no fear, under existing circumstances, that Canadian "hands" will be overtasked. So long as the number and proportion of employers and employed continue as they are, there will be plenty of choice for the latter, and the unreasonable master will soon find himself a marked and avoided man, unable to obtain help when he most needs it; while his less selfish and exacting neighbour will be cheerfully and well served. A kindly and considerate treatment of farm hands, or indeed any class of labourers, will generally enlist them heartily in their employer's service, and establish that mutual interest and good understanding between the contracting parties, without which neither farming nor any other business can be pleasantly and prosperously conducted.

Agricultural Premiums.

The signal advantage to be derived from competition, and the immense aid to progress which the system of agricultural exhibitions and prizes has developed, do not require, in the present day, to be enforced by illustration or argument; but it would be unreasonable to expect that we had reached perfection, and that there was no room for improvement. Indeed, it is now generally acknowledged that the existing class of premiums needs some additions, if not substitutions. There are, for instance, some departments in which the specimens that gain prizes are of comparatively small value. Among live stock, a single excellent animal is of intrinsic worth for breeding purposes, or some other desirable object, and deservedly obtains distinction; but among field or garden products an individual or very limited sample may be raised at a disproportionate cost, and may afford a very inadequate idea of the general character of the crop, or the good management of the producer. Prodigious Swedes are not unfrequently culled from a field of very inferior growth, and mammoth fruits are sometimes merely the pets of a neglected garden, and like the spoiled children of a family, very unfit subjects of reward.

It is with such classes of premiums that there is need of some change, and additions of the character required are being introduced both in Great Britain and in the United States, with very encouraging results. To some of these improvements it may be well briefly to direct the attention of those who have the management of our agricultural exhibitions.

The actual trial of implements with the practical testing of their work is becoming each year more extensively adopted as an essential element in competition. Indeed, there is no other fair indication of merit, and without such test awards are comparatively worthless as a guide to farmers. This feature in the exhibitions of the Royal Society of Great Britain is one of the most noticeable of modern innovations. The trials are very thoroughly and systematically conducted, considerable time being devoted to the purpose, and only a limited class of implements being submitted to examination in each year, so that all may in rotation be fully tested. The New York State Agricultural Society has also set a good example in this same direction, and there can be no doubt that great improvements in agricultural machinery will result from such a system.

Another commendable novelty in this year's prize list of the Royal Society has excited much interest, namely, the award of premiums for the best managed farms. The

competition was confined to the County of Oxford, in which the show was held. The first prize, a silver cup, value £100, was awarded to Mrs. Millington, of Ash Grove Farm, Ardley, Bicester; the second, of £50, to John Treadwell, of Upper Minchenden; besides commendations for other farms, and, in one case, the recommendation of a third prize. The farm of Mrs. Millington, we are told, was by no means a model farm, in the general acceptation of the phrase, with extensive buildings, high-bred stock, steam cultivation, and all the appliances of modern science, but was an ordinary tenant farm, judiciously managed in accordance with a tenant's limited capital, and with a primary view to profit. No doubt the decision of the judges will be sharply criticised, and in future some more specific regulations may be found necessary to determine the awards; but the principle is a sound one, and the example will be followed up by other societies on both sides of the Atlantic.

As a further excellent illustration of this subject the prize list of the New York State Agricultural Society for their forthcoming exhibition may be cited, and is deserving of general imitation. An enumeration of some of the novel objects for which premiums are offered, will show the practical character of the competition, and may suggest valuable hints to some of our own societies. Among the special features to which we allude, are premiums for essays and experiments; for the best specimen of farm book-keeping; the best examples of underdraining, of reclaiming swamp lands, of irrigation; the best experiments with wheat, liquid manure, feeding stock, etc. Besides these, special prizes are offered for tree planting, for crops, for the best vineyard, the best dairy, and the best managed farms. These are all objects of prime importance, and bringing them into prominence by public competition cannot fail to diffuse much valuable information, to stir up a rivalry of the most practical character, and to lead to improved methods of husbandry.

We earnestly commend the subject to the consideration of agricultural societies in our own Dominion.

A Natural Method of Salmon and Trout Raising.

A strict system of preserving fish, similar to the practice adopted with game, was formerly the only method in operation for preventing the gradual extermination of many valuable species; but, in addition to legal restrictions against wholesale or unseasonable slaughter, a far more efficient plan has, within a comparatively recent period, been successfully introduced, not only to arrest the decimation, but to re-stock depopulated waters, and multiply their finny inhabitants almost indefinitely by artificial breeding. This system of pisciculture has been chiefly applied to salmon and trout, as being the most valuable, and perhaps the most easily raised in this way. The subject has occupied considerable attention, and been practically tested on an extensive scale in Europe, and quite recently has begun to attract the notice which its importance deserves, both in the United States and in Canada. The method most generally practised is that of trapping and catching the adult fish during the spawning season, pressing out the ova of the female, and impregnating them with the milt of the male similarly extracted by pressure. To this method objections have been raised as being unnatural and violent, inflicting more or less injury on the parent fish, and from the liability of ejecting immature ova, as well as subsequent artificial treatment, producing a degenerate offspring.

We are not prepared to discuss the force of these objections; but admitting that bungling performances in unskilful hands may give colour to them, and, moreover, that the attention of some prominent pisciculturists has been too much devoted to the lucrative trade of selling ova and very young fish, rather than raising them to maturity, still the very marked success that has attended carefully conducted operations in artificial fish hatching furnishes strong grounds for believing the system to be sound, and the results most advantageous and important. Our object, however, at present, is to direct attention to a simpler and more natural method, which the objectors to the artificial system would substitute for attaining the same object. The matter has been recently brought into public notice by Mr. W. H. Furman, of Maspeth, Queen's County, N. Y., who has devoted much patient investigation to the subject, has tried and at length abandoned the purely artificial method, and proposes instead one which he claims is not only more consonant with nature, but more satisfactory in its results. He has arrived at his conclusions by carefully studying the habits of the fish, and aiming to secure the conditions which are naturally essential or desirable. He observes that the spawning beds must be clean and gravelly, having the water of a certain even temperature, somewhat warmer than the average temperature of the stream. The absence of a strong current, and comparative darkness, are also important; such situations are usually found over springs in the bed of the stream. In the plan which Mr. Furman advocates, he combines all these conditions, and imitates nature as closely as possible.

The main feature of his method is what he calls a shanty, which is simply a commodious, healthy and safe spawning ground. The bottom or bed is composed of a layer of clean gravel from four to eight inches thick. Through this bed, springs, natural or artificial, percolate from underneath. The structure is covered, so as to protect the eggs from the injurious effects of sunlight, and is kept free from eels, frogs, water-snakes, water-rats, muskrats, and other enemies of the young trout.

The shanty having been set in order, the trout are left to find their way to it by natural instinct, which is always sufficient. They flock to the spot at spawning time and deposit their eggs on the gravelly bottom. The eggs immediately sink in the gravel beyond the reach of the male trout or other interlopers. As soon as the eggs begin to hatch, the trout are all driven from the shanty, a screen is put at its mouth to prevent their return, and the young fish are left in absolute safety. They are kept in the shanty, and fed there, till they become old and active enough to be turned out into a pond to take their chance in wider and deeper waters.

The method certainly seems feasible, and we commend a trial of it to those who have suitable streams on their farms; and have no doubt that with comparatively little trouble they may obtain an acceptable variety of wholesome food for their own tables, as well as increase the profits of their husbandry by supplying the market with the produce of the waters in addition to the fruits of the earth.

Quebec Provincial Exhibition.

The Council of Agriculture for the Province of Quebec have issued their regulations and prize list for the forthcoming exhibition, to be held in Montreal during the third week in September, from the 13th to the 16th inclusive. The occasion will, no doubt, be one of great interest, and the more so from its occurring less frequently than our own exhibition, being a biennial instead of an annual affair. Extensive preparations in buildings and grounds are in progress, and the Council, under the energetic leadership of the President, H. G. Joly, Esq., and M. H. Cochrane, Esq., the Vice-President, are bestirring themselves to render the exhibition of this year one that shall eclipse its predecessors. The presence of Mr. Cochrane's stock alone would render the show peculiarly attractive, and repay the visitor for the trouble of a long journey. Others also in the sister Province have been stimulated by his example, and have recently made valuable importations from Great Britain, and these will, no doubt, be on view as competitors for distinction. The time fixed is early, and has been so arranged as not to interfere either with the New York State Fair, or our own Provincial Exhibition, and the occasion will, doubtless, draw a large crowd to Montreal. The Council, we are informed, will make arrangements with steamboat and railroad proprietors for carrying passengers and articles at reduced rates, and also with the Customs Department for the free entry into the Province of articles for exhibition.

The competition is open to all; and intending exhibitors are notified that all entries for live stock must be made on printed forms supplied by the Secretary, Mr. Leclerc, of Montreal, on or before Saturday, August 27th,

two weeks preceding the show. Entries in other classes may be made up to Saturday, September 3rd, one week preceding the show, after which date no entries will be received.

In the list of premiums—a liberal one mounting up to nearly $9,000, more than $5,000 of which are offered for the live stock department—there are some special features. The Prince of Wales Prize of $50 is offered for the best herd of cattle, consisting of one bull and five cows, no specification, however, being made as to breed. The Council also offer a second prize of $50 for the herd next in merit. The classification of horses is somewhat peculiar, as giving prominence to special breeds—Clydes, Percherons, Normandy, Suffolk, and pure Canadian—for each of which three prizes are offered. A nnmber of other varieties are also embraced in this olass, and among them—last and least—Shetland ponies are included. In cattle also a diminutive breed, but one of world-wide celebrity, the Alderney, comes in for a share of honours. At the last exhibition, two years ago, there was a beautiful herd of these animals shown that had been recently imported from England, and selected chiefly from the Prince Consort's farm

The absence of any horticultural department challenges comment; but is no donbt accounted for by the fact of the Montreal Horticultural Society taking this branch under their special charge. They will assuredly hold their show simultaneously with the Agricultural and Industrial Exhibition of the Province, and thns supply what would otherwise be a grave deficiency. We trust the efforts of the Council will be amply rewarded, and that the forthcoming competition will be at once an evidence of progress, and an incentive to yet further advancement in agriculture and the industrial arts.

Encouraging the Importation of Thoroughbred Stock.

The Provincial Association have, during the present and past years, adopted the following resolution, which has been published in their prize liat, appended to class 23 :—

"With a view of encoursging largely the importation of improved stock, the exhibitor of any male animal imported into this Province from Great Britain or any foreign country, and not previouly exhibited, which ahall take the first prize in any of the above classes, will be paid three times the amount of the premium offered in the list; the exhibitor of any female animal imported and not previously exhibited, taking the first prize, will be paid double the amount offered. Such animals to be the *bona fide* property of persons residing in Ontario (Upper Canada) and to be retained in the Province for at least twelve months after obtaining the prize. Satisfactory evidence must have been given at the time of making the entry that the animal has been imported, and not previouly exhibited at any Ontario Provincial Show, or the increased prize will not be paid."

This, one would think, was clearly enough expressed, and yet there are persons who ask what it means, and contend that it violates the principle of open competition, restricting it to the Province of Ontario; whereas no one outside is precluded from obtaining his prize should he gain one, but he is not entitled to the *extra* premium for importation, unless the animal is retained in the country for a certain period. This is certainly only a reasenable stipulation, for it could not be expected that Ontario should offer any special inducements or rewards for importations into New York or other States for the exclusive benefit of those countries.

There is certainly another rule, the 12th, which will practically exclude exhibitors of male animals over one year old, in the horse and cattle classes, from taking a prize, unless they diapose of them to a resident, or allow them to serve in Ontario for one year after the Exhibition closes. This also we think only just and reasonsble. The only improvement we would suggest is the offer of special prizes designed to encourage the importation into the Province of improved stock, even in cases where other imported animals may take precedence in the awards. Newly-imported animals, provided they are commended by the judges as being of good quality and real value for the improvement of our live stock, might be allowed an extra premium, whether they gained a prize in their reapective classes or not. The importation of a really valuable animal deserves some such recognition and reward.

Galt Sheep Fair and Ram Sale.

A number of enterprising gentlemen, of the counties of Waterloo and Wellington, have determined to have an annual fair at Galt, on a similar plan to the well-known Kelso Tup Sale of Scotland. The first fair will be held on the 14th October next, when it is hoped the inauguratiou will be well attended by all the prominent sheep-breeders of Ontario. There is expected to be a large number of buyers from the United States, as the fair is extensively advertised in U. S. agricultural journals. It will be optional with breeders to sell by auction or private sale, though the former mode will have the preference with most of them. Galt is situated on a branch line of the Great Western Railway, and is easily accessible from all points on the G. T. R. via Guelph, and G. W. R. via Harrisburg. The notice of the fair will be found in our advertising columns.

NATIONAL LIVE STOCK JOURNAL.—We have received the first number of this new periodical published at Chicago, and edited by J. P. Reynolds. It is a handsome, well printed quarto magazine of 32 pages, containing much valuable information. A long list of its special correspondents and contributors includes the names of some of the leading stock-breeders and agricultural authorities of the Western States. It is published monthly, at three dollars per annum.

KELSO RAM SALE.—The annual autumn show of sheep and ram sale has been announced to take place at Kelso, Scotland, on the 9th of September. We expect shortly to receive full dctails.

MORETON LODGE COTSWOLDS.—We direct the attention of sheep-breeders to the advertisement in our present issue of Mr. Stone's Cotswold sheep sale, to take place at Moreton Lodge on the 21st of this month. We are informed that the sheep are all closely shorn, and in good breeding condition.

SALE OF YOUNG THOROUGHBRED SHORTHORN BULLS.—It will be seen by our advertising columns that Hon. D. Chriatie offers for sale a number of his young Short-horn bulls. These choice animals are in excellent condition, and show unmiatakable evidence of the Booth blood they inherit through their sire, Knight of St. George.

IMPORTATION OF THOROUGHBRED STOCK.—We are informed that George Isaac, Esq., of the Haldimand Plains, Northumberland County, has made a second importation of thorough-bred Short-horns from Scotland. This importation consists of two bulls and seven heifers, three of the heifers being two-year olds and the others yearlings. They were selected by Mr. George Isaac's son, from the well-known herd of Mr. Sylvester Campbell, Aberdeenshire. It is gratifying to observe that so many Canadian stock-breeders are giving evidence of their enterprising spirit by making valuable importations from Great Britain.

FOUR-HORSE POWER THRESHING MACHINE.—Farmers have often felt the want of a convenient threaher, of smaller size than the ordinary travelling machine, and the price of which would bring it within the reach of men of ordinary means, so that it might be included among the regular implements of the farm, and be at hand when it was required, thus obviating the necessity, in busy and pressing seasons, of waiting the convenience of others. Such a private machine could also be worked by fewer hands, and at much less cost than the ordinary thresher, a consideration of no small consequence to the farmer himself, and to his good wife, on whom a large share of the extra toil of threshing days devolves A machine of this kind has been now some time before the public, and has each year gained in favour. We believe that the "Little Giant Thresher," manufactured by Mr. James Sharman, of Stratford, and advertised in the present issue, is thoroughly reliable, and possesses all the advantages which the maker claims for it. It is of moderate price, can be worked with four or six horses, but is preferred by many who have used it to the larger machines. One of its chief excellencies, we underatand, is that it threshes clean and without waste. It will be on view at the Provincial Exhibition.

Horticulture.

EDITOR—D. W. BEADLE,
CORRESPONDING MEMBER OF THE ROYAL HORTICULTURAL SOCIETY, ENGLAND.

Fruit Growers' Association of Ontario.

REPORT FOR 1869.

We lay before our readers another extract from this valuable report, containing the information given concerning fruit-growing in that part of the Province known as the Lake Ontario section, East Division, embracing the counties of Frontenac, Addington and Lennox, Hastings, Prince Edward, Northumberland, Durham, Ontario and York.

APPLES—The following apples are recommended in the order named below, as most suitable to be planted, namely, Early Harvest, Fameuse or Snow-apple, Northern Spy, Rhode Island Greening, American Golden Russet, St. Lawrence, Red Astracan, Spitzenburgh, Baldwin, Talman Sweet, Twenty-Ounce Apple, or Cayuga Redstreak; King of Tompkins County, Early Strawberry, Golden Sweet, Ribston Pippin, Gravenstein, Sweet Bough, Duchess of Oldenburgh, Roxbnry Rnsset, Wagener, Alexander, Fall Pippin, Swaar, Kentish Fill Basket, Bellflower, Summer Qneen, Seek-no-Further, Cabashea, Pomme Grise, Keswick Codlin, Winesap, Vandevere, Nonsuch.

The following thirteen varieties were most numerously recommended in the order given, as profitable for market, namely, Northern Spy, American Golden Russet, Rhode Island Greening, Fameuse or Snow-apple, Early Harvest, Spitzenburgh, Red Astracan, Baldwin, St. Lawrence, Talman Sweet, Twenty-ounce Apple, Duchess of Oldenburgh, Gravenstein.

The following ten varieties are the most nnmerously named in the order given below, as being the most hardy, namely, Northern Spy, American Golden Russet, Fameuse, Red Astracan, St. Lawrence, Talman Sweet, Early Harvest, Rhode Island Greening, Ribston Pippin, and Duchess of Oldenburgh.

The following are mentioned as being tender, especially when planted inland, remote from the influence of the lake, namely, Baldwin, Esopus, Spitzenburgh, Sweet Bough, Fall Pippin, Rhode Island Greening, Bellflower, Early Harvest, Cabashea, Colvert, Hawley, and Jersey Sweet.

The apple trees are considerably infested with the borer. Some complaint is made also of the tent caterpillar and bark louse, and one mentions the fire-blight. The fruit is somewhat affected by the codlin moth, but this insect does not seem to have, on the whole, become very troublesome.

The spring is recommended by all as the best season for transplanting, though some advise that the trees be taken up in the fall and heeled in.

DWARF TREES—Dwarf apple trees succeed well. Dwarf pear trees require some shelter, and to have the quince roots, upon which the pear is worked, protected by a mulch or covering of coarse manure spread upon the ground over the roots. Dwarf cherry trees are reported to succeed better than the standard.

PEARS.—The following varieties of pear are reported as desirable sorts to plant, namely, Flemish Beauty, Bartlett, Vicar of Winkfield, Louise Bonne de Jersey, Seckel, Buffam, Belle Lucrative, Resticzer, Howell, Beurre d'Amanlis, Glout Morceau, Passe Colmar, Swan's Orange, Osband's Summer, Sheldon, Lawrence, Winter Nelis, White Doyenne, and Jargonelle. Of these peara the Flemish Beauty is evidently the most popular; Mr. Werden says it is the best out of seventy kinds.

Many state that they do not know the names of the sorts which have proved to be too tender, but the following are mentioned by others, namely, Bartlett, Buffam, Belle Lucrative, White Doyenne, Tyson, Henry IV., Beurre Bosc, Beurre Diel, Duchess d' Angouleme, and Easter Beurre.

Mr. P. C. Dempsey says, "there are several varieties planted that appear tender when young, such as the Bartlett, Beurre Clairgeau, Doyenne du Comice, &c., still they appear to become more hardy if grown on suitable soil, well drained, unless the tree is allowed to overload. Several varieties have failed with me entirely, but I am not ready to cast them out without another trial on different soil. In testing a new variety now, I plant on different soils. My convictions are that soil and cultivation have something to do with the hardihood of a tree."

The Flemish Beauty is the most frequently named as the most profitable for market, and next to it the Bartlett, with the Vicar of Winkfield, Louise Bonne de Jersey and Duchess d'Angouleme, in the order above set down.

The most hardy varieties are Flemish Beauty and Vicar of Winkfield. With regard to these there is no difference of opinion; concerning the Buffam, White Doyenne, Tyson, Duchess d'Angouleme and Louise Bonne de Jersey there seems to be some conflict of experience.

The fire-blight prevails to a considerable extent, and mention is made of leaf-blight and frost. The slug on the leaf has done some injury.

PLUMS.—The plum trees seem to thrive well in this division. Many sorts are mentioned—the Lombard, Washington, Yellow Egg, Yellow Gage, Coe's Golden Drop, Imperial Gage, Jefferson and Duane's Purple, the most frequently.

The Huling's Superb, Smith's Orleans, Monroe, Red Magnum Bonum, Peach Plum and Victoria are the only sorts spoken of as being too tender. All plums are reported as being profitable and finding a ready sale, yet the Yellow Egg, Lombard, Yellow Gage and Duane's Purple seem to stand out the most prominently.

The curculio has evidently found his way very generally into this division, and is reported as injuring the fruit by nearly every observer. The black knot also prevails to a very greatextent. Mr. Werden says that to wash with lye and put ashes round the roots is the best remedy for the black knot.

CHERRIES.—The Morello and Duke varieties of cherry may be generally cultivated in this part of the country, and in warm, dry soils and sheltered situations some of the Heart and Bigarreau varieties, such as Elton, Napoleon Bigarreau, Black Tartarian and Knight's Early Black can be grown. Mr. Werden says he has tried twenty sorts of cherries, and feund them all too tender.

The common pie or Kentish cherry is found to bear most uniformly and abundantly, and on that account to be the most profitable market sort in this section.

There is a disease similar to the black knot on the plum, which seems to be very prevalent in this division. Mention is made of the slug on the leaf, and of the curculio as stinging the fruit, but these do not seem to be very serious. Mr. Werden complains of the climate as being the most injurious with him.

PEACH, ETC.—The peach, quince, apricot, and nectarine will not succeed in this division. Mr. James, of Napanee, however, says the qnince can be grown.

STRAWBERRIES.—Strawberries thrive well. Wilson's Albany and Triomphe de Gand are very generally named as succeeding well, and the Wilson's Albany takes the lead for market purpeses.

RASPBERRIES.—Raspberries seem to thrive well in this part of the country. In some sections the wild sorts are very abundant. The Fastelff, Brinkle's Orange, Doolittle, Philadelphia, Franconia, and Red Antwerp are mentioned as having been grown with entire success.

GOOSEBERRIES.—The Houghton seedling gooseberry has here been found not aubject to mildew, while in by far the greater part of this division the English varieties are badly injured by it. The Crownbob, Whitesmith, and Ploughboy are spoken of as heing the least affected of the English sorts. Messrs. Charles James and Charles Anderson say that there is no mildew on the fruit.

Fleur of sulphur, planting on rich clay soil, with clean cultivation and thorough pruning, are mentioned as preventivo of mildew. Mr. Chaplin says a dry soil and open place will help the same, but the boys are the best preventive; they steal them before they are large enough to mildew.

BLACKBERRIES.—The Lawton or New Rochelle blackberry has been tried in seme places, but it has been found too tender. No other sort seems to have been tried. Wild sorts grow in some parts very abundantly.

CURRANTS.—Currants of all kinds can be grown. The White Grape, Black Naples, and Cherry currants seem to he the most popular. Within a few years past the sawfly worm has been very destructive to the foliage, thereby causing the death of the bushes, but it is also said that by a little care it can be easily overcome.

GRAPES.—The following varieties of grapes have been planted—the four varieties first named by far the most extensively, namely, Delaware, Isabella, Clinton, Concord, Hartford Prolific, Iona, Allen's Hybrid, Catawba, Diana, Adirondac, Rebecca, Israella, Union Village, Creveling, Tokalen, Diana Hamburgh, Walter, Agawam or Rogers 15, Barry or Rogers 43, Lindley or Rogers 9, Massaseit or Rogers 3, Merrimack or Rogers 19, Salem or Rogers 22, Wilder or Rogers 4, and Rogers Nos. 5, 14, 28, 33,39, 40, 41, and 44, and Brown's White and Brown's Red, the two latter having originated in Brighton, the white being much like the Sweetwater.

The great majority of the replies speak of most of these varieties as doing well; one mentions the Rebecca as too tender, another says the Isabella and Catawba need protection in winter, a few say that all should be laid down and covered in winter. Mr. Werden alone says that all, except the Clinton, are too tender. The Clinton, Delaware, and Concord are frequently spoken of as being perfectly hardy.

The Delaware, Isabella, Clinton, Concord, Hartford Prolific, Allen's Hybrid and Adirondac, are mentioned as ripening their fruit every season. Mr. Dempsey says that hardy varieties like the Delaware have never been attacked by any insects or by mildew, and that he thinks the township of Ameliasburg a very favourable section for the cultivation of the vine. Mr. Thomas Brownlie says there is a small vineyard in Scarboro' of about four hundred vines, chiefly Delawares.

Mr. Werden, of Picton, says that grapes ripen there about once in three years, and that it is too cold generally.

SOILS.—Mr. Farley says that in West Hastings what is known as their Oak-hill land is fine for apples, plums or cherries, as good as can be found east of Toronto. They find that any naturally dry land is good for fruit.

Mr. Thomas Briggs, of Kingston, says the soil is generally strong clay, varying, however, in different localities—some black soil. Fruits succeed best in a loamy or sandy loam soil, with a fair mixture of clay.

Mr. Werden says that in Prince Edward county there is a great variety of soil. Trees do best in loamy soil with a limestone bottom, especially in moist seasons, but in times of extreme droughts they do better on a more heavy soil. Extreme droughts prevail between Cobourg and Prescott, supposed to be on account of the clearing off of the forests, hence the necessity of planting out forest trees. His orchard is on rather high land—loamy and gravelly surface with a limestone bottom, and surrounded with a heavy belt of trees. He adds that there is an old seedling tree in that vicinity equally as good as peaches for canning or preserving, but he does not say what sort of a tree it is. He thinks that Prince Edward County yields as many barrels of cider and apples as any in the Dominion.

Mr. John Shields, of Prescott, says their region is too cold for fruit raising.

Strawberries.

To the Editor.

SIR,—Several articles have appeared in the GLOBE and other papers, regarding the crop of strawberries this season at Oakville and other places, but I do not think that any of the localities can compete with the county of Brant, in regard to yield.

Mr. J. T. Charlton, near Newport, had one and seven-eighths acres under crop this season, of which one and a half acres were Wilson's Albany Seedling, and three-eighths of an acre of other sorts, comprising New Jersey Scarlet, Green Prolific, &c.

From the Wilson his crop was 6787 quarts, and from the other sorts 300 quarts. It will be seen from this that the yield from the Wilson is by far the largest in proportion, they producing over 4,500 quarts per acre, and the other sorts (all yielding about an equal crop) only 800 quarts per acre. The Wilson also brought the same price in the market. The average price paid to Mr. Charlton for his whole crop was 9½ cents per quart.

This is the heaviest yield of strawberries yet reported, and had this season been equal to last the yield would have been one-third larger.

W. S.

Brant, Aug., 1870.

The Currant-Worm.

Having had a severe fight with the currant worm, and conquered the enemy, I send you the mode of attack. The worm made its appearance here three years ago, and has grown worse each year. Since its first appearance, previous to this year, I have tried whale-oil soap, four pounds to thirty-two gallons of water and carbolic acid; but not finding either of the above effectual as I could wish, I began to use kerosene oil till it would kill the worm. I used five pounds of whale-oil soap, and one wine quart of kerosene to twenty-five gallons of soft water. Stir the soap and kerosene till thoroughly mixed; add two pails of hot water; stir till the soap is dissolved, then add the balance of the water cold, when it is ready for use. Apply with a syringe with force, in bright sunshine. I do it in the middle of the forenoon. Since I have used this solution I have had few currant-worms, after three applications in bright sunshine. The sun dries the leaves, whereas, if applied in the evening, as is the custom with many, the falling dew gives the worm a chance to revive, so as to go on with its work of destruction the following day.—*Geo. Cruickshanks in Tilton's Journal of Horticulture.*

To which the editor adds:—Besides the above, we are informed that an intelligent and observant horticulturist has found a solution of copperas, in the proportion of one pound to six gallons of water, sprinkled on the leaves, a sure preventive and remedy for the currant-worm, by poisoning their food so that they die in a few hours.

Window Gardening.

Many of our readers take much pleasure in keeping a few plants in their windows, and are always glad of any hints that will help them in the pleasant task of caring for their favourites. Walter H. Bosanquet, Esq., delivered a lecture some time ago at the National Schoolroom of St. George's, Bloomsbury, on this subject, which was printed by request, and we condense from that lecture some thoughts and suggestions which we hope will prove acceptable.

Success in window-gardening depends on constant attention being paid to a variety of small things.

Plants are active during the hours of light, and absorb from the air carbonic acid gas, which is composed of carbon and oxygen. Animals retain the oxygen and give out the carbon, hence plants feed upon that—the carbon—which is injurious to us. At night, however, plants give out carbonic acid in small quantity, hence it is undesirable that they should be in our sitting-rooms or sleeping-rooms at night. But at night plants should be, and naturally are, in a state of comparative rest; daylight having departed, the temperature falls, and the air becomes several degrees cooler. But our sitting-rooms are usually warmer at night, we draw the curtains, poke up the fire, and at least keep up the heat of the room, so that the plants are kept in a state of restless and unnatural excitement, when they ought to be at rest. The effect of all this upon them is much the same as the effect upon us of being kept up night after night, and no sleep during the day. To obviate this must be a part of your care, doing it in such a way as may be most convenient, but in some way reducing the temperature about the plants, yet not so low as to chill them, much less to freeze them.

The size of the pot should conform to the size of the plant, but usually the most convenient size is the one that measures four or six inches across the top, inside the rim. A new pot should be placed for a few minutes in a pail of water to expel the dry air from the pores, and an old pot should be made perfectly clean inside and out. Pieces of broken crock, or charcoal or half-inch bones, should be put into the bottom of the pot, to the depth of about two inches, for drainage, and over these a little moss, or anything to prevent the soil from washing into and choking up the drainage. As for soil, any good garden loam will answer; if it be very strong clay, it might be improved by mixing with it some pure sand. A little turf piled up and allowed to rot, forms one of the best of soils for all pot plants. Put the larger and coarse pieces at the bottom, on top of the drainage, and the finer mould over them, filling the pot to within half an inch of the surface. In order that the air may have access to the roots, the surface of the soil must not be allowed to cake, but should be stirred up occasionally as deep as can be done without injury to the roots. The root should not be allowed to suffer from sudden changes of temperature, and especially should not be exposed to the direct rays of a hot sun falling on the pot. This may be prevented by placing the pot containing the plant inside a larger pot, and filling the space between the two with moss, or any other non-conducting material.

Watering needs to be carefully done. The effect of watering is two-fold; it conveys to the root certain nourishing matters contained in the water itself, and it converts into a fit state for absorption by the roots the nourishing matters which are contained in the soil; for the roots can absorb nourishment only when it is in a liquid state. The best water for plants is rain water, for it contains the largest supply of air and other matters calculated to advance the growth of a plant. If it becomes necessary to use hard water, put into it a little soda, and let it stand in the sun some time before it is used. When watering is done it should be thorough and decided, and then let alone until again required. Judgment must be used in every case, and the plants watered when they need it, and not because a certain hour of the day has arrived. Never merely wet the surface, and leave the roots below without moisture, but moisten the whole ball of earth within the pot. If you have good drainage the surplus water will run out into the saucer, which should be thrown out as soon as you have done watering, except that in very warm and dry weather a very small quantity may be allowed to remain in the saucer. The water should never be colder than the atmosphere in which the plants are living, and should be carefully poured over the surface of the soil, not over the plant. Plants need a season of rest. In this climate the winter is that season, and when at rest plants will need only just sufficient warmth and moisture to keep them alive. Plants intended for winter growth should have a month or two of rest at the end of the summer.

At night plants should be left in the dark, and have a lower temperature than during the day; but on the return of day they should be freely exposed to the light so long as the day continues, only shading them when the sun is hot. They should stand as close to the window as may be practicable, and the pots turned every day or two, that all parts may be equally exposed to the light. There should be no scarcity of light, for this is absolutely necessary to enable the leaves to discharge their functions properly. When the plants are taking their annual rest, there is not the same need of abundance of light.

Plants also need a constant supply of fresh air, therefore the window should be open as much as possible during mild weather; yet, while they are benefitted by a liberal supply of fresh air, they are injured by being exposed to draughts. If plants are kept in warm rooms, closely shut up, they become very sensitive, and liable to suffer acutely at any sudden fall of temperature. If, on the contrary, they are frequently and freely exposed to fresh air, they become more hardy, and better able to bear sudden changes of temperature.

Another important consideration is cleanliness. The leaves of plants are perforated with thousands of small pores, the same as the human skin. Through these pores the plants breathe as it were, absorbing carbon and giving out oxygen, and through these they absorb and give out moisture. Now, if a plant be coated with dust it is quite unable to perform any of these functions. It is therefore necessary to keep the leaves of plants clean, and when they get dusty, wash them. Wash each leaf with a sponge and warm water, and if they are very dirty use a little soap, and after the washing has been completed, dip the whole of the top in clean, tepid water. But much can be done in the way of prevention, which is better than cure. They should be kept from getting dusty as much as possible. When the room is swept and dusted, the plants may be removed to another room, or a light cloth or sheet thrown over them to prevent the dust from settling on the leaves. When the air is dry and warm it is well to sprinkle the leaves with a little water; this will afford a supply of moisture to the plants. But the leaves should never be washed or sprinkled while the sun is shining directly upon them, they must be kept out of the sunshine until they are perfectly dry. There is a natural method of washing the foliage that can be often resorted to, namely, that of placing the plants out in a gentle rain, but it will not follow that because they have been out in the rain they have also been watered, for if the leaves cover the pot they will be likely to shed off the rain beyond the rim, so that the soil in the pot will have been but partially moistened

The foregoing hints are intended to apply to the growing of all window plants, without particularizing the peculiar treatment which is applicable to any particular kind of plant. Those will be most successful who study the peculiar habits of the plants they desire to cultivate, and do not try to grow in the same window, or in the same room, plants of such opposite habits that the temperature and moisture of atmosphere best suited to one portion is wholly unsuited to another. The Camellia requires a cool and moist atmosphere, and will flourish with a northern exposure where it has little or no direct sunshine. The Rose will flourish with less moisture, but prefers a cool temperature. The Fuchsia is fond of both warmth and moisture, but does not like long exposure to the direct rays of the sun. The Coleus requires plenty of heat and moisture, and indeed prefers that the thermometer should never fall below seventy by night or day. The Geranium is probably the most easily grown of all window plants, only provided that it has abundance of light and air, and not too much heat. Since the advent of double Geraniums there is less need of multiplying kinds of plants, as with the Rose, Fuchsia, and Geranium, one can command a great variety and one of exceeding beauty, while by a careful attention to air, light and cleanliness plants may easily be kept healthy and vigorous.

Brantford Flower Show.

The Directors of the Brantford Horticultural Society held their first show this season on the 1st July, in the drill shed of that town. The exhibition was a very good one, and was well attended. The articles for exhibition were placed on three tables, each sixty feet long and six feet wide, having the flowers in the centre, and fruit and vegetables on each side. The floral table was well filled, and showed some very good plants, and although short of greenhouse plants, yet the large quantity of plants exhibited, (otherwise grown), fully made up for the loss.

Among the most noticeable of these were some fine Coleus belonging to Mr. Sanderson, who took the first and second prizes for foliage plants. The Hon. E. B. Wood was awarded the prizes for greenhouse plants and Pelargoniums. Mr. Sanderson also took the first prize for Balsams in pots. Bouquets, both hand and table, were very poor, only two or three really nice being shown, and the best in each class were awarded the second prizes. Some fine Petunias and Verbenas were shown, also Zinnias and other annuals. Of collections of annuals some very fine lots were on the table, more especially those exhibited by amateurs, among which those shown by Mrs. Veal, Mrs. Gale and Mrs. Smith, were the best. A large table bouquet of native flowers, shown by Mr. Peachio, was much admired. A collection of native flowers named was shown by Mr.

Sanderson, and included some specimens of *Lilium Canadense, Lilium Philadelphicum, Cypripedium spectabile, Calopogon pulchellus, Castillega Coccinea*, etc. The same party also exhibited a Wardian Case, filled with native ferns, which attracted much attention. The amateurs shewed some fine pot plants, most observable of which were good specimens of Gloire de Nancy Geranium, Double Petunias, Fuchsias, and a very large lot of fine Balsams, also a few large Oleanders, the largest of which, shown by Mr. Wilkes, was awarded the first prize, and was a very fine plant just coming into full flower.

The fruit table was very scanty, but had the usual show of apples and cherries, the latter very fine; the best quart was shown by Mr. W. A. Smith, named Cleveland Bigarreau. Mr. Smith also took the first prize for four varieties with Yellow Spanish, Cleveland Bigarreau, Black Eagle and Black Tartarian. Currants, red, white and black, in good show; also a few bottles of grape wine were on the table.

The vegetable department was well represented, and some very fine things were exhibited. In beans, onions, lettuce, etc., there was plenty of competition. In potatoes, Early Rose was the chief competiter, and were very fine; Breeze's King of the Earlies was also on exhibition; it is not so large a variety as the Rose, but a very fine potato. In beets there were large lots exhibited, both long and turnip. In the latter class, a new beet, called Egyptian, was shown, and awarded the first and second prizes, being very handsome, dark coloured and of fine quality. Collections of vegetables were also shown, including very large varieties of vegetables.

The Band of the Grand Trunk Railway was in attendance during the evening, and the exhibition was well patronized by the townspeople, who recognize the exhibitions of the Horticultural Society as standing institutions of the town.

This exhibition was in effect the best yet held in Brantford for a summer show; nearly every article exhibited was excellent, and would compare very favourably with any other society exhibition at same dates. There was a falling off from the number of entries made for last 1st of July, but the quality of nearly everything was very much superior to what was exhibited at that time. —*Communicated.*

Use of Wind-Breaks.

Belts of trees—deciduous and evergreen—will break off the wind from a large tract of land, and render the local climate comparatively mild and equable. The effects of a screen of evergreens, particularly in breaking off the wind from houses and grounds, and in modifying the cold of winter, is far greater than one supposes who has had no experience in this matter. It is said by those who have made the experiment, that the expense of planting such trees about a house is soon covered by the saving of fuel occasioned by the shelter they afford. Such belts may not break off all the winds that blow, but they will soften their asperity, and apparently mitigate their coldness.

Experiments of this kind have been tried on sea-shores, and with success. A recent traveller speaks of a certain district in England, on the cliffs of the German Ocean, which had formerly been a bleak, sterile promontory, but is now a beautiful and productive garden. And this transformation was effected by building on the exposed sides, first a "strong, high fence of furze bundles or brushwood, and then planting inside of this a thick screen of trees." These trees consisted chiefly of the Norfolk black willow, Scotch elm, larch, and ash; and of evergreens, the *Pinus pinaster* and Scotch pine. These trees were fringed with such shrubs as the snowberry, alder and herberry.

In visiting several fruit-orchards near Cayuga Lake, last summer, we noticed that two of the very best were shielded on the north and west sides by screens of Norway spruce. A single row of these trees answered the purpose, and they were set out the same year that the orchards were planted.—The American arbor-vitæ (the common white cedar) and the hemlock spruce, would answer an excellent purpose as wind-breaks, the only objection to the latter being the difficulty of transplanting it.

But enough has been said to illustrate the importance of shelter, and to suggest some of the means by which such protection may be secured. We need it at all seasons of the year, but especially in winter. We need it for the comfort and pleasantness of our homes, for the comfort and health of our labourers and of our domestic animals, and for the complete success of our attempts to cultivate well the earth.—*Hearth and Home.*

Bark-Splitting of Apple Trees—Black Knot on Plum Trees.

To the Editor.

SIR,—My apple trees have suffered also from the splitting of the bark, mentioned in the CANADA FARMER. I have one hundred trees that have been set out three years, and one hundred that have been planted eleven years, and nearly one-third of them have the bark split. I have two hundred older trees, that are not hurt. The bark split at the time of the first freeze; when I first saw them the ground had frozen very little. The way I account for it is this, that the sap was yet up when the trees were frozen. I have worked in orchards over thirty years, and I never knew the winter set in when the trees were so green before, and I think that to be the sole cause. In my older trees the split is healing fast. Some of the youngest are split on two sides, and the bark is loose nearly all round the tree, and these are very pale-looking. Mr. Tayler, of St. Catharines, speaks of splitting the bark with a knife; but this is quite different, the knife does not loosen the bark.

If Mr. Squelch will examine his plum trees closely in August or September, he will find a worm in the knot. I have kept mine clean by searching closely about August, and cutting the knots off and burning them. If he will leave but two or three on he will have plenty next summer.

H. H.

Pelham, July, 1870.

Peas.

T. R. Elliott writes to the *Rural New Yorker* that Carter's First Crop Pea, sown for several years at the same time with other early kinds, is always from four to six days ahead of all the rest, and is the most productive. Sutton's Ringleader he finds to come in from a week to ten days later, and to perfect its crop gradually. Tom Thumb, Little Gem, Dan. O'Rourke and Prince Albert are not as early as Carter's First Crop, and not as valuable for a second early pea as Waites' Caractacus. McLean's Advancer follows Caractacus, and, for a Wrinkled Marrow, early and good, but not profitable for market, Yorkshire Hero has proved this year more productive and profitable than Champion of England.

NOTE BY EDITOR.—The Advancer Pea is a dwarf-growing sort, and on that account preferable, requiring no bushing or support. Its quality is of the very best.

Washes for Fruit Trees.

Twice a year, at least, every fruit tree in the orchard should be washed with some liquid, strong enough to destroy the eggs and pupæ of insects, and the roots and spores of mosses and fungi. In using caustic ley for the destruction of bark lice, several persons have killed their trees, as sometimes the bark turns black and peels off after the application of this wash, and the death of the tree follows. Lime whitewash is recommended by some persons, but it is unsightly and is disapproved of by the most experienced fruit growers; soap suds are harmless, but are too mild for the purpose for which the application is required. The most suitable wash is a solution of common sal-soda in the proportions of one pound of soda to a gallon of water. Rain water is the best for this purpose. This wash will not injure the bark, but will kill the eggs or pupæ of insects, and will clear away mosses, etc. It will remove dead bark and produce a healthy surface.—*Western Rural.*

PRESERVING PLUMS FOR EXHIBITION.—A subscriber from Richmond wishes to know "which is the most effectual method of preserving early plums for fall exhibitions?" If any of our readers can give the desired information they will confer a favour.

Marantas, or Calatheas.

Amongst pictorial-leaved plants there are few that can compare with the beautiful species of Maranta which have of late years been introduced. The Begonias are, some of them perhaps, equally striking as to colour, but they are mostly wanting in the refinement of character which is a prominent feature in the Marantas. Did we say Marantas? Well, that is, perhaps, a moot point. Some at least of them have been determined on good authority to be Calatheas, and it is assumed that many, if not all of them, are so; but, whether Calatheas or not, there is probably no family which has so rapidly as this filled up its ranks with distinct and beautiful forms.

MARANTA VEITCHII.

The Maranta Veitchii (admirably figured in the accompanying illustration,) occupies, in my estimation, the first place in point of beauty, on account of the size and rich and varied colouring of its leaves, the paler portions of which are transparent, and contrast most admirably with the purple and dark green tints of the upper and lower surface. Closely allied to it, however, in aspect, and scarcely, if at all, inferior to it in beauty, comes M. Lindeniana, a plant of the same character, and with similar colouring in the leaves. M. Vanden Heckei is a smaller-growing species of the same type, referred by some authors, as a variety, to M. picturata.

Of another type, but also of exquisite beauty, is the M. rosco-picta, whose rounder leaves have shorter footstalks than in the foregoing, and are most charmingly tinted with darker and paler green, and marked by a rose-coloured zone. M. illustris is a variety of this according to Dr. Regel's opinion, but, variety or not, it is a most ornamental plant, being barred transversely with light and dark green, and zoned with pink. Under the name of M. ornata (but not the ornata of Veitch), Dr. Regel brings together sundry beautiful forms known as albo-lineata, rosco-lineata, regalis, and majestica, which are marked by transverse lines of bright colour, red or white, on a green ground. Another set has green leaves with white zones, M. virginalis being one of the most striking, with its broad almost orbicular leaves, and white band and costa; M. Baraquiniana is smaller, with ovate-lanceolate leaves, and broader belts of white on each side the costa.

Still another beautiful type is represented by M. splendida, which has the leaves of a deep bright green, with transverse yellow grand bands, looking very much as if a pale green pinnate fern had been painted on the Maranta leaf. Mr. Veitch's original ornata was of this type, only the fern portrait was dark green on a pale ground. The old M. zebrina is another most beautiful plant, as our exhibitions sometimes testify.

Space would, however, fail to note the many charming objects which this genus presents, and I pass on to observe that, as stove plants, they are by no means difficult

to grow. What they need is liberal treatment. In spring, when they may be divided if necessary, or taken to start on into growth, they require a brisk moist heat to be maintained about them. Later, when growth is mature, they may be used to decorate the temperate conservatory. The soil should be fibry peat and sharp silver sand, with an admixture of charcoal fragments, and at the last potting, of a little sweet fibry loam; and the drainage must be good, as they require an abundance of water while growing freely. During winter they should be at rest, and should have comparatively little moisture at the roots.—C. A. in *Gardener's Chronicle.*

Twice-fruiting Raspberries.

A correspondent, writing from Bowmanville, states that he has a yellow fruited raspberry which was "very nearly all killed by the winter," and that he is surprised to find that the canes which have grown up this season are nearly all bearing fruit, and wishes to know whether these same canes will bear fruit again next year.

Had our correspondent been able to give us the name of the variety of the yellow raspberry, we should then have known whether it was one of those which bear fruit twice the same season.

The Belle de Fontenoy, Lum's Yellow Canada, and others of this class, give a crop of fruit on the canes of last year, when not winter-killed, which ripens at the usual raspberry season, and another crop upon the canes that come up during the summer, that ripens in the autumn.

If our correspondent's variety is one of the autumn bearing sorts, then those canes which have come up from the roots this summer will ripen their present crop in the autumn, and bear another crop next season, that will ripen at midsummer. But it is quite possible that his variety is not one of those that fruit twice in a season, and that the shoots which are now showing fruit have not come up from the root, but have branched out from the cane that was injured by the winter at a point very near the ground, and below the injury. If this be the case, these branches will this year bear fruit that will ripen a little later than the ordinary season of raspberries, but will not bear fruit again next season.

We think our correspondent will be able, by examining these fruit-bearing shoots, to determine whether they spring from the canes of last year, or from the roots, and so decide whether they may be expected to bear fruit another year.

APPLE SUCKERS.—A correspondent enquires "which is the best way to prevent apple trees from growing young shoots or suckers around the roots?" Healthy apple trees do not send up such shoots, unless the soil has been removed from the collar, so as to expose some part of the root. Such shoots are the result of disease, injury, or bad treatment.

The New Roses.

"D., Deal," writes to the *Cottage Gardener* an account of the new roses of 1868 and 1869 which were exhibited at the Royal Horticultural Society's show, from which we make such extracts as will be of interest to our Canadian readers.

Thyra Hammerich is a very pretty blush-white rose, with shell-like petals, formed somewhat in the style of Baronne Prevost, only a little more cupped.

Souvenir de Monsieur Poiteau has come very rough this season, but its colour will always insure it a welcome.

Mademoiselle Eugenie Verdier is a very pretty rose, and likely to be an acquisition.

Marquise de Mortemart is an undoubtedly good rose in a section where good roses are much wanted, blush white.

Emilie Hansbury, a prettily shaped pale rose, and with imbricated petals.

Dupuy-Jamain, a beautiful carmine rose, well worthy of cultivation.

Victor le Bihan, beautiful, bright rosy carmine.

Monsieur Journeaux is of a very peculiar shade of colour—reddish scarlet with a purplish tinge through it—good form and large.

But to my mind, the finest flower of the season is Louis Van Houtte. It is of the shade of the old Cabbage Rose, and has also its fine perfume. In colour it is like Charles Lefebre when it comes dark, approaching at times to that of Prince Camille de Rohan.

There is another rose, whose position is now so well established that it is not needful to say much of it, but I question if at the show there was one rose which sooner caught the eye and held captive the beholder than Duke of Edinburgh. In brilliancy of colour it is unsurpassed, while its fine habit gives it also a claim which many dark roses do not possess.

Bark-Splitting.

To the Editor.

SIR,—As my theory of bark-splitting is different from any I have noticed in the papers, permit me to present it for consideration. As far as my experience goes, spring is the only season when it is to be discovered. According to circumstances the evil may be detected earlier, or later in the season. A careful examination of the trees as the snow disappears, will probably lead to the conclusion that the injury has been done then. Who has not noticed, on a melting day, basins formed around the trees? If the evening succeeding is frosty, and circumstances favourable, a collar of ice will be formed at the bottom of the basin, and around the tree. Perhaps a cold spell sets in, and the collar tightens around the tree and the bark is injured, particularly if the growth has been vigorous the preceding year. Your correspondent's heaps of dung and mounds of earth afforded the very facilities necessary for the formation of the icy band. I am not sure but the treading of the snow around the trees, to prevent the approach of mice, may have the same effect. One of my dwarf apples I found to be badly injured last spring, and I concluded it was destroyed; but with a vague hope that it might survive, I gathered a mound of earth around it, and with some fruit and foliage a little paler than usual, it still gives indication of vitality.

With my girdled trees—of which I had a good number—I have tried different experiments, uniting the bark above and below with scions, covering all up with a mound of earth; plastering with cow-dung and clay, adding the mound; boxing the tree and filling in with different materials, such as mud, soil and cow-dung. Some of the younger ones I simply painted, some with blue paint, and others with water lime and milk. One stately tree I removed from the garden to the orchard, forming a band of clay around the girdled part, and wrapping it around with a rope of withered grass. Strange to say, they are, without exception, alive and living-like at the present time.

Trees with split bark, I am persuaded, may be saved by scions uniting the separated parts after the injured bark has been cut off. If the operation is carefully performed, and proves successful, valuable trees may thus be preserved. I believe the addition of the mound of earth to be always important.

WALTER MILNE.

Nithbury.

More New Raspberries.

The *Rural New Yorker* gives an engraving of a new raspberry, called the Herstine, and a description of it, and of three others, the Ruby, Saunders and Elizabeth.

The Herstine is reported by the Fruit Committee of the Pennsylvania Horticultural Society to be a most abundant bearer, fruit large, crimson colour, flavour sub-acid and very good.

Ruby is reported as being an abundant bearer, fruit large, of a dark crimson colour, flavour sub-acid and excellent.

Saunders is said to be a good bearer, fruit very large, of a crimson colour, of high character, and delicious.

Elizabeth they say is a great bearer, fruit very large, crimson-scarlet, firm, of delicious flavour, and late in ripening.

These were raised from seed of the Allen raspberry, grown on plants which fruited in close proximity to the Philadelphia, and are thought to show signs of crossing between these two sorts.

The report of the committee is in too general terms to enable the reader to form any very distinct idea of the distinguishing qualities of these new raspberries. We can not tell whether they are as hardy and productive as the Philadelphia, or whether they can compare in flavour with the Col. Wilder or Brinckle's Orange, or in size and firmness with the Franconia. However, as these

plants are now offered for sale at the *very low price* (!) of three dollars each ! ! any one who is very curious to know more of these new fruits can get a plant of each for a pound note, and find out for himself.

Pansies from Seed.

The Pansy, *viola tri-color*, is deservedly a favourite with amateur, as well as professional florists, and should be more generally cultivated. It is easily grown from seed, delights in a rich and rather moist soil, which is best prepared by digging the ground deep, pulverizing it well, and making a liberal addition of well decomposed cow manure. The seed should be fresh, as its vitality is not of great duration. In out-door cultivation the seed may be sown during July and August, in rows, and quite thin, that the young plants may attain a good fall growth. At any good seed store may be obtained seed of both the English and German varieties; the latter furnishing the greater proportion of the light-coloured and fancy varieties.

After the young plants are well up, keep the ground free from weeds, well stirred, and if very dry, water thoroughly. The plants may remain in the seed-bed during winter, protected by some evergreen or other brush, and some of the waste vines from the vegetable garden. The bed should be well drained to prevent the action of frost affecting the plants injuriously. When plants are wanted for early spring blooming or sale, they are best wintered in a cold frame in rich soil. Covering the glass with mats, set them at sufficient distance apart to allow of good spring growth. As they flourish in quite cold weather the mats may be removed early in spring, when they will at once begin to grow, and come early to bloom.

For later planting they are best wintered in the original seed bed, and transplanted where desired at time of setting other bedding plants; with good cultivation they will come soon into bloom, and continue up to the hot weather of summer, if picked freely.

Very large flowers are obtained by a liberal use of fertilizers. The best, for the purpose, is obtained by filling a barrel from the cow-yard, and leaching this with rain or river water, and applying the liquor diluted to the roots of the plants. Amateurs form a cup-shaped cavity around the roots, fill with the liquid manure and cover it with soil, sprinkling the plants with fresh water afterwards to keep the foliage clean. As they will bloom but little during hot weather, unless freely watered, the large stalks may be cut off, and new shoots allowed to grow, which will become vigorous during the fall, and bloom until covered with snow; indeed, we have gathered fine bouquets of bloom during a thaw at the holidays.

As the plants come into bloom, those not showing flowers of colours clear and well defined, should at once be removed. Those in which the colours run, or blend, so as to give them a greenish or muddy appearance, are not worth cultivation. The standard shape of the flower when the leaves are flattened on the hand, is that they should be nearly a circle, and, under good culture, as large as a silver half dollar. By placing a variety of the most desirable colours and forms in one bed, a first-class seed may be grown, and the general variety very much improved. As the seed pods burst at maturity, much care is needed to secure seed in any amount. Those who desire plants only for bedding out, can obtain a good supply by stirring the soil lightly, and allowing them to grow where dropped. A little care in selecting good form and colours, will enable the cultivator to soon possess a very desirable collection.

In this connection we may say this is the appropriate season for sowing the seeds of such biennial and perennial flowers as it is desirable to transplant early the ensuing spring for summer blooming. Always sow upon a well prepared seed bed, where they will not be affected by water during winter, and protect with brush and refuse of the garden, care being taken that the plants are not covered so as to smother or rot them.—*Rural New Yorker.*

Planting Apple Orchards.—Distance Apart.

Mr. F. R. Elliott, of Ohio, is one of the ablest horticulturists of the day, and his thoughts upon any matter, especially relative to fruits and fruit culture, are well worthy of a careful consideration. In a recent number of the *Rural New Yorker* is an article from his pen, entitled "Dwarf Apple Trees," in the course of which he seems to be thinking aloud on the question of distance apart most desirable for an orchard of standard apple trees, and as his thoughts are not mere day-dreams based on nothing, but the calm reasonings that spring from experience, and his conclusions such as have been forced upon his convictions against the bias of inherited example and general practice, we lay them before our readers, remarking only that the force of his suggestions is rather augmented than diminished by the difference of climate between Ohio and Ontario:—

I set out in life with the orchards of my father as my early study, and there the trees were forty feet apart. I read author after author, each of whom carried their teaching in true rotation, and as I now view it, based only upon the wants of the apple tree when it reaches its full maturity. Thought and reference to the different habits in growth, their upright or spreading forms, have never, or rarely, been touched upon; nor has the comparative value of shade of the soil, as an ameliorating item conditional with the health of the tree, been duly considered by advisers as to the distance at which to plant trees; and even at this day, I read articles saying:—"Plant your apple trees thirty-five to forty feet apart." Now, I have no action to take with such advisers; it is their view, and is worth what it is worth; to many, it is correct and wise; to me it is the reverse.

In 1850 I commenced a specimen orchard of apple trees, and planted them twenty feet apart, a distance which all my friends said would require at least every other tree to be removed in ten years. The trees did well, for I gave them good care. Then the property passed from my hands, but it has been well cared for, and I have had opportunity to watch its growth, and now twenty years have passed, and the trees do not shade more than one-half of the surface of the ground. In the production of other crops it has been of no value, as in working the orchard the roots, &c., gave more trouble than the value of any crop obtained. Had I planted those trees ten feet, or even eight feet apart, and cultivated for them alone until the trees were too large for cultivation, and then mulched, I am satisfied that I, or whoever was the owner, would have gained thereby, for the space, in the time, would not have been more than fully occupied, and had the trees been kept headed back, say by pruning in July, the crop would have been annual and profitable, while the other half or two-thirds of the land could have been used for other crops, free from the annoyance of working among trees.

In 1863 I set out another orchard of standard apples, each sixteen feet apart, and at the same time I set the same number of dwarfs on the Doucain stock, each six by five feet. The results are that on the former I have gathered say two to three bushels of fruit, and on the latter fifteen to twenty; but now my dwarfs are loaded, while my standard orchard has perhaps two bushels for the year.

Taking all things into account, estimating the soils of our Western prairie or new lands, the extremes of heat and cold of our climates, the severe storms of wind to which we are subject, etc., I am free to confess that at this time I am an advocate of closer planting than has heretofore been generally practised or advised. I am satisfied I see a gain in protection and shade from the first. I see a gain in the crop for ten years, considering the extent of land and the value of culture used, by planting eight feet instead of thirty feet or even twenty feet apart. I see a health and vigour, a less liability to injury and decay from severe action of sun or storms, in the thickly planted orchard as compared with that to which we must look forward thirty years for its maturity, and I am disposed to think we have paid too little attention to a stock on which to work choice sorts, that when grown will bring them early into bearing, and once in bearing help to prevent our having to thin them out, if inadvertently we have planted a little too closely.

Our Vines and Vine Trellis.

Last spring, the old fence against which our vines were trained was blown down. It had been erected fifteen or twenty years, the posts had become much decayed, and the boards scarcely less so. I was not sorry to see it overthrown by a heavy south-west wind, but how to mend the loss became our next care, and many plans pro and con were mooted and in turn rejected. Finally, the plan of posts and wire was substituted for a fence to train the vines on. The distance was about 160 or 170 feet.

One day in early spring, when time did not press for other things, I procured some pieces of scantling and small round cedar posts, and set them about fourteen feet apart and 3½ feet deep, having first planed them smooth and finished them in a sightly manner. I put the first post deeply and strongly into the earth, and as it had to bear the pull of the wires, I placed across it, at the surface of the earth, but buried below it, a piece of scantling two feet long. This was required to afford resistance to the pull of the wires. Each post projected 4½ feet above the earth, and was bored at intervals of one foot, with four half-inch auger holes, and then all being put in level and of an even height, they presented a very neat and pretty appearance. I next obtained 650 feet of wire, about as large as a wheat straw at the ear, and passed it through the holes in the posts, after taking a turn round the first one.

You will see that there was thus formed a straight, handsome wire fence to train the vines on, but the wires were slack, and I was so pleased with their appearance, so far, that I determined to have them tight and straight as a fiddle-string. I therefore braced the last post as I had the first, with the piece of scantling, and taking the projecting end of the wire where it passed through the last post, winding it around a stick, and setting my feet firmly against the post, I was enabled to put a heavy strain on the wire, so much so as to make it as straight as an arrow and as tight as possible from end to end. A dexterous twist around the post, without letting back in the least, securely fastened the end, and this was repeated with each wire, and I had as handsome a trellis as one could wish. We trained the vines part one way and part another, and wove them around the wires, fastening them where refractory and refusing to lie close, with twine.

It is now August, and we have a handsome hedge of vines, trimmed here and there to keep it within bounds, which forms a beautiful boundary, and at the same time affords abundance of grapes. We find the Hartford Prolific, Concord, and Delaware, succeed admirably with us. We manure them most abundantly, of which more by and by, when we see the result.

Last year was one of great hardship for vines. Few about here had any grapes ripen, and I saw numbers of vines whose fruit was green and shrivelled when the frost came, whilst ours were as abundant as ever, and ripened to perfection. We attributed it to the manure used; and if it answers as well this year as formerly, I shall certainly ventilate the plan through your columns.

C.

NOTE BY THE EDITOR.—C. will do well to loosen his wires at the approach of winter, lest the contraction of the wires by cold either loosen the posts or snap the wires

Fruit Growers' Association of Ontario.

The autumn general meeting of this Association will be held in the Town Hall, St. Catharines, on Thursday, the 22nd day of September, 1870, at 11 o'clock, A.M.

Members are requested to bring with them samples of such fruit as may be in season, especially of grapes, pears, plums, and crab apples, for comparison. It is expected that there will be a fine show of grapes in particular, especially if members will all contribute what they can. Those who cannot come to the meeting may send samples by express to the Secretary.

The following subjects are suggested for discussion :—

THE GRAPE VINE.—1. Best methods of pruning and training. 2. Best method of grafting. 3. Best method of manuring. 4. Winter protection. 5. Destruction of insects. 6. Earliest varieties.

PEAR TREES.—1. Their cultivation. 2. Pruning. 3. Manuring.

CRAB APPLES.—The best sorts, and their economic uses.

Members are requested to read or cause to be read to the meeting papers or short essays on any branch of fruit culture, especially any facts of interest that have come to their knowledge, or fallen to their experience.

Members will please report at the same time on the growth of the Eumelan grape.

By order.

D. W. BEADLE,
Secretary.

St. Catharines, Sept. 6, 1870.

FRUIT IN NEW YORK CITY.—There seems to have been an over-supply of fruit in the New York market. The *Rural New Yorker* says that on Tuesday, July 26th, many of the finest Lawton blackberries ever raised were left to spoil for want of buyers, though offered at four to six cents per quart. Raspberries were sold by the car-lead at four cents per quart. Apples, too, have been largely in excess of the demand. Selling at $2 to $3 per barrel.

Our Garden.

"Our Garden"—How much there is in these two words, so much of home and its attractions, good for father, mother, children and all. But to have a garden worthy of the name, we must not expect only to work with a plough and team for about three days in spring, and do no more all the remaining part of the year. A mere vegetable patch is not worthy of the name of "Our garden." What I mean by a garden is some lawn, plenty of deciduous trees, and some evergreens in their proper place, good orchard trees, and vines, with a plentiful portion appropriated for vegetables and small fruits. This garden will require work and attention, and if of any extent, no doubt the time required will sometimes be ill spared, but the garden is such an ornament and luxury that all are ready to put a hand to its decoration. Odd hours are continually occurring, in which much may be done. Then the vegetables are such an addition to house-keeping; often and often there has been wanted in the country something for dinner and tea besides just perk and potatoes, bread and butter. A good garden has always something to be found in it for such a purpose; peas, beans, cauliflower, tomatoes, rhubarb, radishes, squash, cabbage, onions, beets, etc.; all these things are most useful, and they will repay the time, care and trouble of raising them. Not to mention flowers, fruits of all kinds, gooseberries, currants, apples, pears, blackberries, raspberries, all are to be had in abundance for just the trouble of planting, manuring, and keeping free from weeds; and what an addition to housekeeping these form.

Often in cities, and particularly in their environs, do we see an acre, and sometimes much more of meadow land, around two sides of a nice house, with trees scattered about, every little depression made something of, and forming a great attraction by its neatness alone; and such a meadow on a more extensive scale, with such trees, is within the reach of every farmer in the land. There is absolutely no expense whatever attending it after planting, as sheep will crop the grass without injury to the trees, and mowing is quite unnecessary. You may depend on it, to bring up a family with such an addition to their home, is to give the first strong inducement to the girls or boys to possess such a home of their own, and they will ultimately have one. Their minds are set towards it, and having always been used to it, will not readily dispense with such. Bear this in mind, fathers and mothers, and if you desire your children's welfare, and that they should like home, devote two or three acres about your homestead to meadow, trees, garden and walks, and a drive up to the house through them.

C.

NOTE.—When will our well-to-do farmers act upon such suggestions as these, and make each home, to the members of each family, the prettiest spot on earth, and our Canadian home the most beautiful and attractive country of this Continent.

A truthful and circumstantial biography in all its relations of a single insect, has yet to be written.—A. S. PACKARD, Jr.

MUSHROOMS.—Directions respecting the method of growing mushrooms were given in the CANADA FARMER for September, and that of December, 1869. The spawn can generally be obtained from seedsmen.

FRUIT AT NEWPORT, ONT.—Mr. James Cowherd writes to the Secretary of the Fruit Growers' Association:—"All my best seedling peaches and apples are in fruit this year. Apples are a good crop, and fairer in appearance than last year. Cherries have been a good crop. Peaches and plums are a fair crop. The pear blight has appeared again; it has not yet done as much damage as last year.

STRAWBERRIES AND RASPBERRIES.—A correspondent of the *Rural New Yorker*, writing from Kentucky, says that the Wilson is, beyond all cavil, the best market berry yet propagated. Green Prolific is large, beautiful and attractive, and almost equal in productiveness to the Wilson, and he esteems it above all others for home use and a near market. He says the Philadelphia is the most prolific of all the red raspberries, flavour quite fair, canes very hardy; and the Mammoth Cluster the largest of all the Black Caps, and enormously productive.

PREVENTION OF MILDEW ON ROSE TREES.—This season the Rose trees in my garden have been kept free from green fly by syringing them two or three times, at intervals, with a wash costing less than 2d. the gallon. I make it thus—Pour 1 gallon of boiling water on 12 ozs. of African aloes and 3 ozs. of potash, and add 16 ozs. of soft soap and 10 gallons of water. This mixture is valuable as a dip; it will keep good for two or three weeks —*Cottage Gardener.*

CRANBERRIES.—Three or four years ago I transplanted cranberry vines from my meadow to one of my gardens, which is pine plain land. They have grown well, and they are now loaded with fruit. I had compromised with them; that if they would come and live with me on my land, I would bring them their native soil, so that they would not suffer by emigration. I dug channels two feet wide, twenty inches deep, and three feet apart. I removed the gravel, and filled the channels with muck from whence they were to be taken. I took up the cranberry plants, in small clusters, and set them deep in their natural element. They appeared to be perfectly contented with their new locality. They now occupy one square rod of ground, and they are beginning to enlarge their borders. I keep this patch clear of weeds. The expense of this cranberry square rod was about two days' labour of one man, and one day's labour of one horse. The prospect now is that the cranberries will yearly pay expenses of their new settlement. Muck and experiments well directed will prove successful.—*Journal of Agriculture.*

Poetry.

Old Age.

The light of spring, the summer glow, are o'er,
And I rejoice in knowing that for me
The woodbine and the roses bloom no more;
The tender green is gone from field and tree;
Brown barren sprays stand clear against the blue,
And leaves fall fast, and let the truthful sunlight through.

What is there to regret? Why should I mourn
To leave the forest and the march behind,
Or toward the rank, low meadows sadly turn,
Since here another loveliness I find,
Safer and not less beautiful and blest,
With glimpses, faint and far, of the long wished-for Rest.

And so I drop the roses from my hand,
And let the thorn-pricks heal, and take my way
Down hill, across a fair and peaceful land,
Lapt in the golden calm of dying day,
Glad that the night is near, and glad to know
That, rough or smooth the way. I have not far to go.

Art Thou Living Yet?

Is there no grand, immortal sphere
Beyond this realm of broken ties,
To fill the wants that mock us here,
And dry the tears from weeping eyes;
Where winter melts in endless spring,
And June stands near with deathless flowers;
Where we may hear the dear ones sing
Who loved us in this world of ours?
I ask, and lo, my cheeks are wet
With tears for one I cannot see.
Oh, mother, art thou living yet,
And dost thou still remember me?

I feel thy kisses o'er me thrill,
Thou unseen angel of my life;
I hear thy hymns around me trill
An undertone to care and strife.
Thy tender eyes upon me shine,
As from a being glorified;
Till I am thine and thou art mine,
And I forget that thou hast died.
I almost lose each vain regret,
In visions of a life to be;
But, mother, art thou living yet,
And dost thou still remember me?

The spring times bloom, the summers fade,
The winters blow along my way;
But over every light and shade
Thy memory lives by night and day.
It soothes to sleep my wildest pain,
Like some sweet song that cannot die,
And like the murmur of the main,
Grows deeper when the storm is nigh.
I know the brightest stars that set,
Return to bless the yearning sea;
But, mother, art thou living yet,
And dost thou still remember me?

I sometimes think thy soul comes back,
From o'er the dark and silent stream,
Where last we watched thy shining track,
To these green hills of which we dream;
Thy loving arms around me twine,
My cheeks bloom younger in thy breath,
Till thou art mine, and I am thine,
Without a thought of pain or death.
And yet, at times, mine eyes are wet,
With tears for her I cannot see—
Oh, mother, art thou living yet,
And dost thou still remember me?

Household.

Painting and Oiling Furniture and Floors.

We had several wooden chairs that were originally of good quality, but years of use had rubbed off the paint, and caused them to look worn and shabby. They had been superseded by more handsome cane-seated articles, and the wooden ones were, as a matter of course, condemned to the lumber-room. Examining them one day, I selected four of the best and least injured, and painted them green, and they are now a great convenience, as well as quite an ornament to our garden.

I like painting, and am subject to periodical attacks of it. When I once begin, and see how much every article is improved by two thin coats of paint, laid on carefully, and well dried before using, it seems as if I never could stop; every article is so much benefited. This year the attack reached its culminating point, and I commenced painting the house, and was much pleased by the greatly increased comfort and improved appearance arising therefrom.

At first I confined myself to the back steps and porch, wooden structures roughly put up, and which had never been painted. The amendment extended to the repair of brickwork, and some ornamented facing boards all round the gable, which were also painted afterwards. The window-blinds and window-seats were also gone over, and even the kitchen floor threatened; but here the higher powers interfered, and I was near being expelled, paint-pots and all—a warning against improvers going too far. Not that the lady of the household objected to the appearance of paint, or even the smell, but the truth must be told—painting floors had been tried on an amateur scale two or three times, at intervals of some years, and whether the paint was bad, or from some other cause, I do not know, but the success was not great. In fact, it was a dead failure. The paint would not dry and get hard, and I did not even get the credit I deserved, namely, that of wishing to save such eternal scrubbing.

I always blamed the paint, and have reason to warn amateur painters against falling into the same error. I used ochre as a groundwork, and I now find that no paint but the best white lead, tinted to stone or other colour, will answer, and this must be used with good boiled linseed oil, with plenty of litharge or dryers in it, combined with some turpentine, and laid on thin, and, as each coat dries, add another. Three coats will usually stand well, and these parts that wear off in those portions of the floor most subject to abrasion must be renewed each summer.

When once any housekeeper has found the

comfort of clean painted floors, she will never again be content with the old, dirty, unpainted boards. In wet weather there must be some mud carried in on the boots, and this is easily removed from a painted floor, by a little cold water. Soap or lye must on no account whatever be used—they totally destroy the paint, and all washes off. Do not forget; never use it, as your floor, if painted, will be ruined. The alkali at once combines with the oil of the paint, and the whole washes off like ordinary clay. I do not yet despair of inducing my wife to allow me to try again.

I was travelling in Tecumseth township some time last year, and took dinner at a house about four miles from Bradford. The kitchen floor was painted, and always had been, and the cracks were all puttied up tight, so that it looked like one board. I asked the lady of the house how she managed it, and from her I derived some very valuable information. She had every floor in her house painted; her husband had done them, and renewed worn parts each spring. She had met with an accident, an injury to the spine, which prevented any bending, so it was manifestly impossible to scrub, and painting was resorted to as a remedy, and a delightful one it proved. A little cold water and a patent mop-stick would remove all dirt quickly, and ten times as fast as a floor could be scrubbed. Some friends of mine, who liked the appearance of the grain of the wood, and yet determined to prevent greasy spots showing, oiled the floor well with raw linseed oil, put on quite hot, and two or three coats were used; but one coat, very thickly applied, provided the oil is very hot, will answer very well, and perhaps better, and as it penetrates into the wood an eighth to a quarter of an inch, it will not wear off like paint, and is equally easily washed. But in heating the oil, recollect never to heat it on a stove, unless it be far away from the house, for there would be great risk of fire from the oil flowing over. Build a small fire away from the house; allow no children about it, and test the heat of the oil with a feather from time to time. If it gets too hot it will burn a feather, and of course spoil your brush, but a little cotton mop is much better to use, and will not injure by heat.

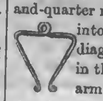
Remember, oil will reach a great heat, far above boiling water, or at all events sufficient to scorch a feather, at which high temperature it would prove dreadfully destructive if an accident were to occur; so be careful if you conclude to use it. I used it for some tables, and it far exceeds paint, as nothing will wear it off.

C.

CEMENT FOR SEALING UP FRUIT.—Take of rosin and brick dust a sufficient quantity; after melting the one, stir in the other. Be careful and not put in too much rosin, or the cement will not hold, and see that the brick dust is finely powdered.

Farm Gongs.

Calling on a friend during one of my wanderings through the north-western part of the County of Perth, I saw an excellent farmer's gong. It was made by taking an inch-and-quarter round bar of English iron, bent into the form of the accompanying diagram, and suspended by the loop in the centre. The length of each arm was about four feet, and when struck with a hammer, produced a ringing, clear sound, easily heard a full mile, and with the wind nearly two miles. This particular shape seems to be the best adapted for the production of sound; without actual experience no one would believe how very loud and clear it was. You will notice that the ends are turned round into a circle of about four inches diameter, and are gradually brought to a point, the iron towards the end being about half an inch in diameter, and the extremity rounded similar to the end of the finger.



This gong was found exceedingly useful, and a regular code of written signals was used, and a copy was always kept hung up close to the gong, so that any one wishing to call for meals struck in accordance; if the proprietor was wanted by a visitor, another series of blows was used; if fire or accident occurred, which required instant attendance, the gong was struck rapidly and forcibly with an iron hammer, in a way quite different from ordinary requirements. Fire did once occur, and it then became every one's duty to run rapidly towards the homestead. These signals being written down and explained, worked to admiration at the time of the fire; the gong certainly saved the house. All were out but the mother when the accident occurred, who, with her little baby, a week old, happened to be the only inmates, and from her recent illness was quite unable to climb the roof and extinguish the flames; but she could beat the gong, and did so, and the unusual signal for fire aroused all within hearing, who hastened to the house, and the fire was easily extinguished. But for the gong the homestead would have been burned to the ground.

The great difference between the sound of the blows produced by an iron hammer and wooden maul was used to especially distinguish the emergency of the case—the sound produced by the wood being heard as far, but not nearly so shrill and sharp.

The cost of such a gong would be trifling, and it would last generations. It ought not to be allowed to become rusted, and a little grease would effectually protect it from oxidation. In bending the circle for the eye, care must be taken not to allow any portion of the bent parts to touch. A small piece of wire will do to hang it to; rope will not answer so well. Common English iron is best, being much more resonant; in fact, the best iron will not answer, as its parts are formed more by lamination, instead of, as in English iron, being crystalline in its formation. The cost of the iron bar will be about $1, and the workmanship about another, and the convenience will amply repay the outlay.

C.

Saddles to Chimneys.

It may be of some use to those building to have a hint on the above very simple expedient to prevent the leaking that usually accompanies the building of chimneys in the roofs of dwelling houses. For the ordinary protection against such trouble, there is what is called flashing, made of tin, zinc or galvanized iron, that lines the gutter immediately behind the chimney. This flashing usually extends somewhere about four to six inches up the side of the chimney, and a similar distance underneath the shingles. Now, it is perfectly clear that during a thaw, and when slush snow lies deep against the chimneys, and the heat of the roof, derived from fires underneath, liquefies the substratum of such snow, it must rise until the force of the column is sufficient to push the mass out of the angle of the chimney formed by the roof, and, meantime, a stream of melted snow is forced back over the flashing, and the rooms below are, of course, inundated, and much mischief often arises.

Now, the remedy is easy and simple. It is to construct a second small roof, called a "saddle," behind each chimney, which being at opposite angles with the main roof, splits the slush snow as it slides down, causing each half to slip past the chimney, and so down to the edge. Much mischief is thus often saved, and at very small expense.

C.

Cider Making.

Those who have orchards of choice grafted fruit will find it more profitable to sell their fruit than make it into cider. But there are still great numbers of farmers, who have old orchards, the fruit of which is of little value except to manufacture into cider.

Like all other undertakings, that of cider making can be well or ill performed, and the profitable result of the process will greatly depend on the care and skill used in manufacture.

The process is usually a very simple one, and the introduction of portable cider mills has so greatly facilitated it that much more care and personal supervision can now be devoted by orchardists to the manufacture of cider from such fruit as may be of small value otherwise.

The first requisite to obtain a good article of cider is to have the fruit fairly ripe, and carefully picked over to reject all decaying and wormy apples. They are then put in heaps for some days to sweat a little, which will improve the flavour. The more sweet apples there are among the fruit used the better will be the cider, and it is always advisable to reject any that are excessively

sour or bitter, and mix in a fair proportion of sweet ones, if they can be had. The apples, when ready to use, are ground up into pulp. This done, the pulp is placed in the cider press, and the juice gradually squeezed out. The pressing must be applied carefully. The cider will be better and of a richer colour if the apples stand for a few hours after being ground or crushed, before applying the pressure to obtain their juice. The great advantage of slow and gradual pressure is that it makes the juice run pure and clear. It is best that the apples should not get mellow before being crushed, as they lose some of their strength and soundness by being allowed to ripen overmuch. It is of the greatest importance to be very careful that no water is allowed to be added in any way during the process of cider-making—the smallest quantity, especially of rain water, will spoil its keeping qualities. Therefore, all the operations must be performed under cover, that no rain may fall on the pomace while it is being pressed. Some grind up the pomace, and press it a second time, but the juice then obtained is generally acrid and gritty, and will spoil that obtained by the first pressing, if added to it. If this second pressing is done, the juice should be saved in separate casks, to be sold as inferior cider.

The casks to be used must be perfectly clean and sweet, and filled quite full, so that when fermentation begins, the froth can discharge at the bung. When the first fermentation abates, cover the bung close with something that can be lifted by the air that escapes during the after-fermentation. In a week, rack off the cider carefully into another clean cask, letting it run only so long as it comes out clear. In ten days more rack it off again, and in fifteen days give it a final racking off. When racked off clear the last time, the cask is to be quite filled, bunged tight, and stored away in a deep dry, frost-proof cellar, there to remain till used.

Perfectly clean, sweet barrels, must be used each time of racking. By attending particularly to the racking process, there will be no occasion for using any artificial substances for fining or clarifying the cider, as it will keep perfectly sound for a long time.

Earth Closets.

A correspondent from Rothsay writes for information as to the construction of earth closets, and wishes to know where he may procure them, and their cost.

The principle on which the apparatus is based is so simple that no complicated or expensive construction is necessary. All that is essential is a supply of dry pulverized earth. This may readily be procured, especially at this season of the year. The soil should be sifted, and, if necessary, spread out in the sun to dry, then stored under cover in any convenient place. A supply of this dry earth may be kept at hand in a box in a closet, by the side of the commode, or wherever it is required; and with an ordinary scoop, about a pint should be thrown over the fœces after each use. A pan or drawer, with a few inches of earth at the bottom, is the only receptacle required, and this can be emptied as often as necessary. For out-door privies, the surface of the earth itself forms a sufficient and a very fit receptacle, and the accumulation may be removed as often as required with a shovel and wheelbarrow. If properly managed, there is absolutely no unpleasant odour.

Though such homely appliances answer the purpose, still, where it can be afforded, some of the more elaborate contrivances, which embody the same principle, but save trouble in the using, are very convenient in the house, and especially in the sick room. There are various patents and different manufacturers claiming public patronage. An English company, under the name of the original inventor, "Moule's Earth Closet Company," have their representatives in this country, and Messrs. Cleverdon & Coombe, of Adelaide Street, Toronto, are their authorised agents for Ontario. This firm supply a very neat-looking earth commode, cased in cherry or other ornamental wood, for $27, or they will furnish the working part—all that is essential—without case, for $12 or $15.

So satisfied are we of the advantages of the dry earth system in an economic and sanitary point of view, that we expect to see its adoption become general; and would especially press the subject on the attention of those who have the management of public institutions, such as prisons, hospitals, factories, schools, and the like. Some trouble may be experienced in cities in procuring the requisite supply of suitable soil; but in the country and at farm-houses, no such impediment is presented, and the plan is not only the most efficacious, but the least troublesome that can be adopted. It should be practised by farmers without exception.

A CHEAP FILTER.—The *Manufacturer and Builder* gives the following directions for a simple filter to purify cistern water: Place on the perforated bottom of a box a piece of flannel, and on this some coarsely powdered charcoal, then some coarse river sand, and cover the whole with sandstone broken into small pieces.

REMEDY FOR ROACHES.—A correspondent in the *Country Gentleman* says that the use of powdered borax where roaches most do congregate is a complete disturber of their visits. The scattering of this sweet, clean and harmless white powder on the shelves, around hot water pipes, sinks, etc., is so repugnant to them, that they at once retire from the field. You, good housekeepers, who have such a horror of these pests, will be glad to learn this.

Agricultural Intelligence.

The Provincial Exhibition.

The Provincial Exhibition buildings have been undergoing large repairs. We are glad to say that the works are in such an advanced state that Mr. Grand, the architect, expected to hand the buildings over to the City Council by the beginning of September.

A new poultry shed, 176 feet by 26 feet, containing 380 coops, has been built on the west end of the grounds.

A new stable, 162 x 30, designed to accommodate 54 horses, has been erected on the north side of the grounds; and three other buildings which have been altered will furnish accommodation for 126 more horses.

On the north side of the ground, just east of the stables, four new buildings have been built for sheep. Two of them are 240 feet long each; the third is 150 feet long; and the length of the fourth is 130 feet. These, with two old buildings that have been altered, contain 290 pens.

On the south side of the road the whole of the old hog pens have been reconstructed. A new building, 180 feet long, contains 60 pens, one 90 feet long containing 30 pens, and one 192 feet long containing 64 pens, have been built. Altogether there will be 216 hog pens.

The three buildings which during the occupation of the Crystal Palace by the 13th Hussars were used as horse stables, have been converted into cattle sheds; and two new cattle sheds have been erected. One of these buildings is 162 feet, and the other 210 feet long. Altogether they contain 192 pens, 30 of which have been specially constructed for bulls.

Two forage barns, 36 x 24 feet each, have been built, one on the north side of the road in front of the horse stables, and the other on the south side in the vicinity of the cattle sheds.

A new shed for implements has been built on the south side of the road, just west of the cattle sheds. Its dimensions are 200 x 25.

For a horse ring, a portion of the ground has been fenced off in the shape of an oblong 400 feet long and 250 wide, with rounded corners. Six cattle rings have also been staked off.

In the Crystal Palace a new gallery rail has been put up; the floors and large doors at the four entrances have been repaired, and the tin work on the roof has been completed. The latter is to receive a coat of Canadian cement roofing. The fountain is being reconstructed in the centre of the hall, and pipes for supplying it with water will be connected with the cupola of the Lunatic Asylum. The carpenter's work has all been completed in the picture gallery, and this portion of the building is all ready to be coloured.

The hall for fruit and flowers has only to receive a coat of whitewash, which will be put on immediately. That portion of the building which it is designed to use for the exhibition of roots, &c.—the old riding school—has been put in proper condition. The inside of the Crystal Palace is not to be painted.

North of the Crystal Palace a ladies' saloon and reception room have been erected.

The fences around and the entrance gates have been thoroughly repaired; a new roof has been put on the building in which the offices are situated, and that and the outbuildings are being painted and plastered.

Royal Society's Show.

This exhibition opened at Oxford on the 11th July, with the trial of implements in the yard, viz: fixed steam-engines, mills, cutters, crushers and dairy utensils. It promised to be one of the best the Society has ever had, as well as the most extensive. The 406 stands for implements would accommodate about 2000 loads. At Manchester there were 384 stands. The 2,976 feet of shedding for cattle, 2,232 for sheep and pigs, is considerably in excess of the provision made at Manchester; but the 213 boxes for horses show a falling off, the number last year being 384. The stock-yard opened a week later, on Monday, the 18th July, and the show of both implements and stock remained open until the evening of Friday, the 22nd.

In the stock department, though the show of horses was smaller than usual, the classes in cattle, sheep and pigs were well filled, and considerably in excess of the numbers at the Manchester show last year. In the Shorthorn classes so large was the show that two sets of judges, one for males, another for females, were required in order to get through the awards in time. In sheep there was a large and fine show of Downs, of which Oxford Downs and Shropshire Downs were most numerous. In the pig classes there was but one recognized breed as a class, the Berkshires; the other classes being large and small white breeds; and the same of black breeds.

In Short-horns the display is said to have been a capital one, but the absence of any of Mr. Booth's stock was noticeable and commented upon. In Aged bulls C. W. Brierly, of Manchester, took 1st with "Bolivar," (25649), an Irish bred bull, that stood first at Manchester last year as a two year old. The 2nd prize fell to C. R. Saunders, Penrith, for Edgar (19680.) This animal stood in the same position at Manchester last year in the aged class. The third prize fell to T. E. Pawlett of Beeston, for "Baron Killerby."

In the two year old class, the 1st went to R. Bruce, Forres, Scotland, for "Scotsman," (27435) an animal that stood first at the Highland Agricultural show last year. The 2nd fell to Col. Towneley for "Baron Hubback," (25569), the reserve bull of last year in the yearling class. J. Wright, Penrith, took 3rd with "Man's Estate." In the yearling class Lady Pigot, of Branches Park, took 1st, Mr. Linton, of York, 2nd; and Lord Braybrooke 3rd. There were a large number of entries in this class, and much dissatisfaction expressed at the awards. The bull calf class was a very promising one, Mr. Dudding of Panton taking 1st prize, and Mr. Stratton of Burderop 2nd. In the aged cow class G. Game took 1st, Lady Pigot 2nd, J. How, Brompton, 3rd. In the two year old class Mr. D. McIntosh, of Havering Park, took 1st with a very noticesbly fine animal, Lady Knightly 2nd.; H. Dudding 2nd, J. How 3rd. The 3 year old class was a very moderate one, the 1st falling to J. A. Mumford, Thaine; 2nd to R. Eastwood Thorneyholme, 3rd to R. Stratton, Burderop. In heifer calves Col. Towneley got 1st, R. Marsh, Offley House, 2nd.

The Herefords were well represented, and Her Majesty the Queen succeeded in taking two prizes and a reserve. 1st for two year old bull, 2nd for aged bull, and a reserve highly commended in the cow class.

The Devons were very fine though not numerous. W. Farthing, J. H. Buller and Viscount Falmouth being the principal prize winners in this class.

The Oxford Prize Farm.

The *Agricultural Gazette* gives an interesting account of a visit to the farm of Mrs. Millington, to whom was awarded, by the Royal Agricultural Society of England, the first prize of £100 for the best managed farm in a specified district about Oxford, where the late exhibition was held. The following particulars of the course adopted will be interesting:—

"The rotation is as follows:—1st, roots, principally Swedes and turnips; 2nd, barley; 3rd, seeds; 4th, two-thirds wheat and one-third barley, including a portion of vetches. Catch crops are seldom sown, and the vetches occupy any portion of the seed land not thought to be in good enough condition to bear a corn crop. Vetches, therefore, on the farm, follow seeds, and are again followed by roots, and this brings any land out of condition into a good state. The rotation is also slightly deviated from by ploughing up some of the seed land early for mustard, afterwards to be followed, like the remaining seed land, with wheat: and the result is said to be two quarters more wheat than after seeds at once ploughed for the wheat crop. Glancing at each crop in rotation, we find that the cultivation for roots embraces one (deep as possible) three-horse furrow in the autumn, followed by steam cultivation in the spring. Up to last year, when Fowler's tackle was employed, Smith's cultivator had been in use. The land is afterwards worked with Coleman's cultivator, and the roots are sown with four cwt, of Hale's superphosphate, put in with water on the flat. Two-thirds of the turnip crop are eaten on the land with cake and corn, and one-third is drawn off for the cattle. No farmyard manure is ever applied to the root crop, but all is devoted to the seed land, and is now being spread over the land as a preparation for wheat, according to Lincolnshire usage. No top-dressings are used; all is put under the soil. Still, oil-cake in the form of sheep-dung is top-dressed on the land, and the condition of the farm must be well supported by the £1,000 to £1,200 worth of cake annually spent on the farm. There is also an expenditure of about £300 per annum in the form of superphosphate, no other purchased manure being imported.

"There is a flock of 400 Lincoln ewes maintained, and all tegs are either fatted or find their way into the flock. Ewes, culls, theaves and lambs constitute a standing flock of 950 sheep, and the clip is estimated at from two to three fleeces per tod. The lambs remain till late with their mothers, as above stated, and the first summer the management appears to be anything but forcing.

"Twenty-five calves are usually weaned every spring upon linseed gruel, and with the assistance of two cows. These cattle are kept until they are three years old, and are then disposed of at from £16 to £18 each. The stores receive from 2 to 5 pounds of linseed cake per day, according to their age, with a restricted amount of roots."

The Wheat Midge in England.

The subjoined extract from a recent English paper bears too plain evidence that the midge is doing mischief in some of the wheat fields of Yorkshire. This pest has of late years been but little known in any portion of the British Islands, nor indeed on the continent of Europe, to anything like the extent, duration or intensity, with which many Canadian and American farmers have unfortunately been too familiar. It would appear that the attack in the cases referred to is of a nature to awaken serious apprehensions:—

"A very serious matter to the Yorkshire farmer, and, indeed, to the country at large, has been detected within the last few days in some parts of Yorkshire. Some of the wheat crops were noticed to be prematurely changing colour, and upon examination it was found that the husks had no kernel, or that, where the kernel yet remained, it was fed upon by numbers of very small yellow maggots, which completely destroy it. In a field near Malton the pest has so overrun the crop that it is scarcely possible to find an uninjured ear of wheat. The forwardest crops are those most flyblown, and in most of the cases the centre rows of wheat in the ear are destroyed. Some of the merchants and farmers, since the discovery was made, have examined crops in various localities, and only in one case, so far—a spring-sown late crop, now in flower—have the caterpillars been absent. It is feared this pest is very widespread, and must seriously affect the yield. Some farmers remember a similar visitation some years ago during a dry, hot summer as at present."

Mr. Cochrane's Importations.

Bell's Messenger says:—Mr. Cochrane, of Canada, has been buying largely at Wetherby and Warlaby. In 1868, when he bought Duchess 97 for 1,000 guineas, he prevailed on Capt. Gunter to let him have another of the family before long. In the spring of the present year he wrote to ask for Duchess 103, which happened to be calved when he was at Wetherby in 1868. This animal Captain Gunter undertook to sell him when he came over. On the 6th July he arrived at Wetherby Grange; and on the 7th, Duchess 103 and Duchess 101 were bought by him for 2,500 guineas. The price of the "promised" one Mr. Cochrane considered was to be the same as that given for Duchess 97, so that the sum paid for Duchess 101 was 1,500 guineas. The *bona fide* sale money for the two is £2,625. Duchess 101 is a red with the usual white on the flank. She was calved in January, 1868, and is by Fourth Duke of Thorndale from Duchess 84. Duchess 103 (the promised one) is a rich roan, calved in August, 1868, and is by Fourth Duke of Thorndale, from Duchess 92, the dam of Duchess 97. These heifers are about four months in calf to Eighth Duke of York, the bull sold in the spring to Messrs. Allen, Tunnicliffe & Bell. At Warlaby, Mr. Cochrane possessed himself, at the cost of 1,500 guineas, of Lady Grateful, the own sister of Lady Fragrant, and, in the opinion of some competent judges, the best Booth cow alive. He also bought Mabel by General Hopewell, and a bull calf, a few months old (Royal Commander, by Commander-in-Chief, from Prudence) for 900 guineas.

Mr. Cochrane's purchases in Yorkshire were not confined to Wetherby and Warlaby. He dealt also at Killerby Hall, buying there Mr. John Booth's Lady of the Lake, a grand red and white cow of November, 1862, for which he gave 500 guineas; Queen of Beauty, red and white, of April 1868, and Fairy Gem, roan, calved in May, 1869. This heifer is twin to Fairy Pearl, which continues in the Killerby herd. The price of Queen of Beauty and Fairy Gem was 500 guineas. The three animals selected by Mr. Cochrane from Mr. John Booth's stock are from his Hecuba family, a very prolific and fine tribe. Lady of the Lake was by Knight Errant (18154), Queen of Beauty by the same bull, from Queen of the Glen by Valasco (15443); and Fairy Gem was by K. C. B. (26492), the son of Knight Errant and Soldier's Dream by Windsor (14013). Mr. Cochrane also bought at Killerby the roan heifer Milliner by Brigade Major (21312), from Lady Percy, bred by Mr. Serjeantson, of Camphill. At Braithwaite he secured a roan bull, and a three-year-old roan heifer of very great merit; the former, calved on the 2nd of September, 1869, Booth's Marksman, by Booth's Kinsman (25658), from Vernal Star by the Sutler (23061); the latter, Rosa Louisa, by Royal Booth (22772), from Rosa Sybilla by Baron Booth (21212), grandam Rose Wreath by Windsor (14013), great-grandam Rose Garland by Baron Warlaby (7813). She is in calf to Regal Booth (27262), the Vesper bull sold a short time ago to Mr. Crosbie, of Ardfert Abbey, Tralee.

Besides the animals mentioned in the preceding article as sold to Mr. Cochrane, Mr. John Booth sold, to Mr. Miller, of Canada, Gaicty, a roan heifer calved in 1867, and got by Brigade Major, from Lady Georgina by Knight Errant; and Madame Booth, a roan calved in July 1867, and got by the same bull, from Vanity by Velasco. Mr. Beattie, moreover, purchased for exportation to Canada, Charms, a red and white heifer of April 1868, by Brigade Major, from Virtue by Velasco.

The *Agricultural Gazette* furnishes the following additional particulars concerning Mr. Cochrane's recent Short-horn and other purchases:—

An interesting catalogue has been published by Mr. Thornton, of the cattle and other domestic animals purchased by Mr. Cochrane, of Hillhurst, Compten, Montreal, We have already noticed the Wetherby, Warlaby, Killerby, and Braithwaite purchases, but besides these, heifers were selected from the herds of Mr. G. S. Foljambe, of Osberton Hall; Mr. Barnes, Westland, Moynalty, Ireland; Rev. J. Storer, Helidon, Davantry; Messrs. Dudding, Panton, and Messrs. G. Garne, of Chipping Norton; J. Christy, of Boynton Hall; R. Plummer, Carlton Husthwaite; W. R. Bromet, Tadcaster, Atherton Chapel House; J. Logan, Newport; D. R. Davies, T. T. Drake, Beattie of Annan, Barclay of Knevil, and Aylmer of West Dereham. Mr. Thornton further informs us that besides these Shorthorns the exportations of 1870 contained a number of first-class sheep and black and white pigs. The sheep comprised the first prize pen of Cotswold ewes at the recent Oxford meeting, bought of Mr. J. Gillett, of Minster Lovell; and fourteen Cotswold ewes and five rams from Mr. H. Coles' stock, also successful at Oxford. A number of pure-bred Berkshire pigs were purchased at Her Majesty's farm, Windsor Castle. Seven pure-bred Berkshires were obtained from Mr. Heber Humfrey; several from Mr. Geo. Griggs, winner of the first prize for boars at Oxford; and four from Mr. Wm. Smith, of Bibury. The white pigs were purchased from Mr. J. T. Robinson, Mr. Aylmer, of West Dereham, and Mr. Atherton. There were also exported two pure-bred Alderney heifers and their calves, purchased immediately after their arrival in England; and a superior-hunting bay mare, four years old, bred by Mr. J. Beattie, Annan, got by Laughing Stock, out of Nanny, by Nimrod, well known in the Cumberland Hunt.

Estimates of the present wheat crop in California fall 2,000,000 centals short of last year.

Automatic Grain Binding.

The *Chicago Republican* gives the following account of the successful trial of a new machine invented by Mr. S. D. Carpenter, of Fond du Lac, Wisconsin, for binding as well as cutting grain:—

"The machine was purposely put to work on all kinds of ground, rough and smooth, hilly and level, to thoroughly test its adaptation to general use upon any kind of surface. It was also tried on standing grain, and in its worst as well as best forms—on tangled, lodged, grassy, weedy, clean and upright—long and short, thick and thin, green and over ripe. The trials were made on the farms of Mr. Sewell, Mr. Thompson, A. J. Birdsall, Mr. Gould, Peter Allard, and E. H. Galloway—gentlemen well known in that section, and whose places all lie within four or five miles of the city. The testimony of those who witnessed the trial is straight and direct that it nowhere failed to do its work—cutting and turning off thousands of perfectly tied bundles, and always in perfect shape where the straw was long enough to give place for the band. Out of 2,900 bundles, it is estimated that not over eight or ten would need rebinding, and this was so short that it was difficult to get the cutter far below the heads.

"One or two small accidents happened during the experiments, but were speedily repaired. It is not possible in a new and untried machine to calculate all the points of greatest strain, until they are demonstrated on trial. None of the discovered defects had anything to do with the principle of the binder, and were mere deficiencies in the strength of one or two parts. Three acres were cut in two hours and a half, without a bundle being missed, and it was believed that, in an ordinarily clear and level field, a span of horses would easily cut and bind eight or ten acres daily, and probably more."

With the addition of an automatic binder, which sooner or later we believe will be accomplished, the labour of harvesting will be reduced to the minimum, and proprietors will be comparatively independent of the extra and expensive help now required in gathering the fruits of the field.

The milk fever is proving quite fatal to the cows in some portions of Portage county, Ohio.

DRAINAGE OF SWAMP LANDS.—Contracts for the drainage of swamp lands in the Province, under the Act passed during the last session of the Provincial Legislature, have been awarded as follows:—In the Township of Grey, County of Huron, George Blain, Malton, $5,945 92; Township of Brooke, County of Lambton, same person, $22,467 99; Township of Mosa, County of Middlesex, Grant & Yorke, Toronto, $9,670; Township of Dunwich, County of Elgin, John A. Philpott, Iona, $9,018 64; Township of Raleigh, County of Kent, John Elliott, Brantford, $30,325; East Tilbury, same person, $24,200.

The Japanese begin to fear that California will obtain the bulk of the trade in silk-worm eggs. In one Japanese city, Yokohama, the trade amounts to $500,000 annually. But it seems that a very destructive parasite has attacked the worms in that country, and it is feared, instead of exporting eggs, it will soon be necessary to import eggs from California to Japan.

The cranberry crop of Cape Cod was much injured by the May frosts. The damage is estimated at not less than $150,000.

The *Ohio Farmer* says that 100,000 pounds of cheese are sometimes shipped in one day from Wellington, Lorrain county, in that State.

A sale of Percheron horses lately took place at West Roxbury, Mass., by the Society for the promotion of Agriculture. Eight animals were sold, two stallions and six mares and fillies—for which the aggregate amount realized was $3,630.

The St. Catharines' *Journal* says the peach crop in that section this year is a complete failure, so complete, indeed, that it is questionable if there will be one thousand bushels to sell. Mr. S. J. J. Brown, one of the largest producers in the district, last year sold over 300 bushels, and this year he cannot fill an order from London for seven baskets. The reports from all parts of the Peninsula is that there will be no peaches.

BEET SUGAR MAKING IN ILLINOIS.—The *Chicago Tribune* gives rather a gloomy account of the prospects of the Germania Sugar Beet Company, whose works are located at Chatsworth, Ill. The writer had just visited the farm, where out of 330 acres in beets this year, 130 are a failure on account of the drought, cut-worm and other causes, leaving 200 acres still standing, but of this area, only 70 acres are very promising. The farm comprises 2,400 acres, one-half of it being in Indian corn, and is managed with great care and skill by the superintendent, Mr. Periam. The 200 acres of beets, for example, are quite free of weeds, which is saying a great deal for such an area in that country. The management of the Company appears to have been less judicious. Many of the farm implements were imported from Germany at great expense, and have little merit for the saving of labor. The local authorities are also blamed for ungenerous and unjust taxation.

From a carefully made up report of the crops of Minnesota, it is ascertained that the wheat crop will only average 14 to 15 bushels to the acre, being 12 per cent. below the average for several years past. The falling off is owing to the drought and unequal distribution of summer rain. The area sown is about the same as last year, namely: Little over a million acres. Owing to the low price of wheat farmers have generally put less land in wheat than formerly. The wheat product of the State will probably reach 15 million bushels, against 18 millions last year. The diminished quantity is, however, compensated by the fact that nearly the whole crop of this year will grade number one. Barley is good, the crop having matured before the recent drought. Oats have suffered more than any other grain, and are light. There is a meagre crop, yielding scarcely 20 bushels to the acre. The corn crop is very large and satisfactory. A largely increased area was planted, and the season has been favourable to its growth.

ESTABLISHED 1840. v2-9-1t

USE NONE BUT THE BEST!!

SOUPS AND BEEF TEA FOR THE MILLION.

STRENGTHENING Nourishment! Economy in house-keeping! LIEBIG'S COMPANY'S EXTRACT OF MEAT, the same that received the highest prizes at Paris, Havre and Amsterdam, and that is supplied to the British, French, Russian, Prussian, and other Governments. None genuine without the signature of Baron Liebig, the inventor, and of Dr. Max V. Petteokofer, delegate, on every jar.
J. MILHAU'S SONS, Company's Agents, 183 Broadway, New York. For sale everywhere. v2-9-3t

PURE BRED POULTRY.

FOR SALE,

A FEW pairs *superior* Houdan and Crève Cœur, bred directly from *imported prize stock*, Dark Brahma (Stephens' stock), Light Brahma, White Cochin, White and Grey Dorking, White Leghorn and Black Spanish, and Royal Java. Also a few Cockerels of each variety.
For further particulars apply to J. W. ACRES, Member Ontario Poultry Association, Box 143 Paris, Ontario. v2-9-1t

THE MORETON LODGE

COTSWOLDS.

Eleventh Annual Sale.

MR. W. S. G. KNOWLES has received instructions from Fred. Wm. Stone, Esq., to sell by Public Auction, without reserve, on

Wednesday, 21st Sept., 1870,

At Moreton Lodge, Guelph, Ontario, Canada, about

40 Cotswold Rams and Ram Lambs.
60 Cotswold Ewes, one shear & over.
10 Southdown Rams.
10 Southdown Ewes.

Luncheon at noon. Sale to commence at 1 *o'clock.*

Guelph is a first-class station on the Grand Trunk Railway, and Trains leaving Suspension Bridge, on Great Western, at 7 a. m., 12.20 p. m., and 5 p. m., reach Guelph respectively at 11.45 a. m., 4.30 p.m., and 9.45 p.m.; and Train leaving Detroit at 8 a. m. arrives at 4.30 p. m. v2-9-1t

THE

"LITTLE GIANT"

THRESHER

—AND—

SEPARATOR,

(FOR A FARMER'S OWN USE),

MADE AT THE

Stratford Agricultural Works,

IS CAPABLE OF

Threshing from 200 to 300 bushels of Wheat, or 400 to 500 bushels of oats per day.

IT THRESHES CLEAN,

And is not liable to throw grain over, having a peculiarly constructed shoe. It has

No Canvas, Elevators or Sieves,

Which in other machines are a continual source of annoyance. The Thresher is simple,

CAN BE WORKED BY ANYONE,

And can be driven with four or six horses. It takes up but little room on the barn floor, and

IS EASILY MOVED ABOUT,

Being placed on wheels. No machine made by me has given such universal satisfaction. It is the best Threshing Machine for a farmer's own use (or even three or four farmers in partnership), while the price places it within the reach of almost everyone.

Price of Thresher alone - - $105
Price of Thresher, with Horse-power Band Wheel or Jack and Belting, $185 *or* $190

Send for a descriptive circular.

JOSEPH SHARMAN,
v2-9-1t Stratford, Ont.

WINDSOR NURSERIES.

Pear Trees for Fall Planting.

ALL judges acknowledge that Pear Trees grown at WINDSOR NURSERIES are the best and hardiest on this Continent.

They are grown on heavy clay loam most suitable for the pear, as witnessed by the gigantic old French Pear Trees growing along the Detroit River. Pear Trees grown on light, sandy soil, of which most Nurseries are composed, are not so thrifty when transplanted.

The present stock of three-year old Dwarf and Standard Pears is the finest ever grown in these Nurseries, and can be confidently recommended as unsurpassed anywhere.

Fall Planting is best for Pear Trees, if only done early enough, as they can be safely lifted a fortnight or three weeks earlier than Apple or most other fruit trees; their young wood maturing earlier, the leaves can be easily removed without injury before lifting, which is absolutely necessary in early fall planting.

Orders for pears should therefore be sent in September, or first week in October (and separate from orders for other trees, which cannot be lifted so early), to allow the trees to be planted by the middle of October. The farther north, the earlier they require to be planted. The stock of four to six years old, bearing Dwarf Pear Trees, is very large and fine.

Catalogues sent free on application.

Trees packed carefully so as to carry any distance safely.

JAMES DOUGALL.
Windsor, 15th August, 1870. v2-9-1t

THOROUGH-BRED STOCK FOR SALE.

100 HEAD SHORT-HORNS, male and female, of all ages, including some fine Bull Calves, HEREFORDS, DEVONS AND AYRSHIRES; LEICESTER, COTSWOLD AND SOUTHDOWN SHEEP, including some fine Rams and Ram Lambs; BERKSHIRE AND SUFFOLK PIGS. Address
v2-9-2t J. MACKELCAN, Yorkville P.O., Ont.

Waltham Watches.

THESE celebrated watches have now fairly won the first position with discriminating watch buyers in Canada, because they are known to be more accurate, more durable and cheaper than any others.

When watches are made on a large scale, as at Waltham, it is true economy to have the best and latest improvements in the art, and it is for this reason that the genuine Waltham Watch greatly surpasses any English Watch which can be had at anything like corresponding price.

The Canadian market is crowded with Swiss Watches bearing names very nearly the same as the trade marks on genuine Waltham Watches.

To avoid imposition, buyers should demand a certificate of genuineness in every case.

For sale by all leading Jewellers in Canada.
v2-9-tf

GREAT SHEEP FARE AND RAM SALE.

AT GALT, ONT., OCT. 14, 1870.

THIS is the first of a series of Annual Fairs after the plan of the celebrated Sheep Fair at Kelso, Scotland, and as it is extensively advertized in U. S. and Canada, Sheep breeders will find it a most advantageous market for the disposal of their surplus stock and their Rams and Ram Lambs. v2-9-1t

VINEGAR. HOW MADE FROM CIDER, Wine, Molasses or Sorghum, in 10 hours, without using drugs. For circular address F. I. SAGE, Vinegar Maker, Cromwell, Ct. v2-9-12t

Steel Tooth Sulky Horse Rake

Will do more work, easier, cleaner, and better than any other. Does not gather dust in the hay. Will rake over rougher ground. Is light and strong, well-made and nicely finished. The teeth are fine spring steel, independent of each other, and will yield to pass obstructions. Took FIRST PRIZE at the Provincial Fair, London, 1869. For testimonials, &c., send for circular. As our manufacture for 1870 is limited, orders should be sent at once.

Responsible Agents Wanted in every County.

NEW ARRANGEMENTS AND GREAT INDUCEMENTS.

Wishing to give more attention to the raising of bees and queens, I offer the following inducements till the close of the coming Provincial Fair:—

To any person sending $3, I will send my single-boarded hive with improved entrance, price $3, or an individual right, price $3, and my dollar book on bee culture, soon to be published; tickets will be sent for the book. For $5, both hive and right, or an Italian queen, and the book. For $10, or the highest bid above that, a right for six weeks, a township right and the book. For $12, or highest bid above that, a township right, one hive, and the book. For $400, or highest bid above that, a right for the entire Province of Quebec, with the exception of two or three counties that are sold; this right is worth $2,500. For $200, or highest bid above that, I will sell a patent for a Self-oiling Buggy Hub, lately introduced; specimen carriage to be seen at Brooklin, Ont.; this patent is worth $2,000. Sale of townships not to interfere with sale of hives upon the above conditions.

J. H. THOMAS,
2-5-tf. *Brooklin, Ont.*

FOR SALE,

SIX high-bred, Young Short-Horn Bulls, one by imported Crown Prince of Athelstane (21,612), 5,487; the others by the Imported *Pure Booth* Bull, "Knight of St. George," (26,544), 6,472.

DOMINION OF CANADA

V. R.

EMIGRATION

TO THE

PROVINCE OF ONTARIO.

To Capitalists,
Tenant Farmers,
Agricultural Labourers,
Mechanics,

DAY LABOURERS,

And all Parties desirous of Improving their Circumstances by Emigrating to a New Country.

THE attention of intending Emigrants is invited to the great advantages presented by the Province of Ontario. Persons living on the interest of their money can easily get eight per cent. on first-class security.

Tenant Farmers with Limited Capital

Can buy and stock a Freehold Estate with the money needed to carry on a small farm in Britain. Good cleared land, with a dwelling and good barn and out-houses upon it, can be purchased in desirable localities at from £4 to £10 Stg. per acre. Farm hands can readily obtain work at good wages. Among the inducements offered to intending Emigrants, by the Government, is

A FREE GRANT OF LAND

(WITHOUT ANY CHARGE WHATEVER.)

Every Head of a family can obtain, on condition of settlement, a FREE GRANT of two hundred acres of land for himself, and one hundred acres additional for each member of his family, male or female, over eighteen years of age.

All Persons over 18 years of age can obtain a FREE GRANT OF 100 ACRES.

The Free Grants are protected by a Homestead Exemption Act, and are not liable to seizure for any debt incurred before the issue of the patent, or for twenty years after its issue. They are within easy access of the front settlements, and are supplied with regular postal communication.

Registers of the Labour Market

And of Improved Farms for sale, are kept at the Immigration Agencies in the Province, and arrangements are made for directing emigrants to those points where employment can be most readily obtained. Several new lines of railway and other public works are in course of construction, or about being commenced, which will afford employment to an almost unlimited number of abourers.

Persons desiring fuller information concerning the Province of Ontario, are invited to apply personally, or by letter, to the Canadian Government Emigration Agents in Europe, viz.: Wm. Dixon, 11 Adam Street, Adelphi, London, W. O.; J. G. Moylan, Dublin; Charles Foy, Belfast; David Shaw, Glasgow; and E. Simays, Continental Agent at Antwerp.

Also to the Emigration Agents in Canada, viz:

John A. Donaldson, Toronto; R. H. Rae, Hamilton; Wm. J. Wills, Ottawa; J. B. Macpherson, Kingston; L. Stafford, Quebec; J. J. Daley, Montreal; E. Clay, Halifax, Nova Scotia; Robert Shives, St. John, and J. G. G. Layton, Miramichi, New Brunswick, from whom pamphlets issued under the authority of the Government of Ontario, containing full particulars in relation to the character and resources of, and the cost of living, wages, &c., in the Province, can be obtained.

JOHN CARLING,
Commissioner of Agriculture and Public Works for the Province of Ontario.

Department of Immigration,
Toronto, October, 1869. v2-2-12h.

BRAHMA FOWLS.

THE largest and finest in the world. Bred from the original *Burnham* importations from China, and same stock as those sent by Mr. B. to **Her Majesty Queen Victoria**, which have taken FIRST PRIZES at all the Fairs, both in England and America, wherever shown. For price and particulars send stamp, and address

v2-9-1t* P. O. Box 131 Melrose, Mass.

Markets.

Toronto Markets.

"CANADA FARMER" Office, Sept. 12th, 1870.

FLOUR AND MEAL.

Prices of breadstuffs generally have tended downwards, in consequence, probably, of the extraordinary course of events in France. Large stocks are consequently held over, and, for the present, prices rule below what is warranted by the actual condition of supply and demand. The following are the latest quotations:—

Flour—Superfine, $5 to $5.10; Spring Wheat, $5 to $5.20; Fancy $5.30 to $5.40; Extra, $5.50 to $5.75.

Oatmeal—$4.50 to $4.60.

Cornmeal—$5.00.

Bran—$9.50 to $10.

GRAIN.

There is but little doing in Wheat, owing to the present uncertain state of the Market. Barley is realizing good prices, with an upward tendency. In other grains the market is quiet.

Wheat—Soules', $1.15 to $1.20; Treadwell, $1.10 to $1.15; Spring, $1 to $1.05.

Barley—Bright, 75c. to 88c., Inferior, 55c.

Oats—38c. to 40c.

Peas—68c. to 70c.

Rye—62c. to 65c.

HAY AND STRAW.

Hay has been in good supply, ranging in price from $10 to $13.

Straw—In fair supply, at $8 to $8.

PROVISIONS.

Trade is moderately active for the season, and stocks rather light.

Live Hogs—$7.

Pork—Mess, $28 to $29.

Bacon—12c. to 13c.

Hams—18c. to 20c.

Lard—12c. to 14c.

Cheese—New, 11¼c. to 12½c.; Old, 13½c. to 14½c.; Reesor's Stilton, 18c.; Royal Arms, 17c.

Butter—18c. to 19c. In rolls, retail, 27c. to 28c.

Eggs—13c to 15c. per dozen.

Dried Apples—6c. to 7c.

Hops—10c. to 15c.

Salt—Goderich, $1.50 to $1.60; American, $1.75; Liverpool, per bag, 75c.

CATTLE MARKET.

There has been a large supply for this season of the year. The following are Toronto prices, dressed weight.

Beeves—From $5 to $8.

Sheep—From $3 to $8.

Calves—From $4 to $7.

Lambs—From $2 to $3.25.

HIDES AND SKINS.

Hides—7c. to 8½c.

Calfskins—11c. to 12½c.

Lambskins—60c.

Wool—25c. to 30c.

New York.—*Flour*—Receipts, 10,000 bbls; sales, 8,000 bbls. at $4.90 to $5.05 for superfine State and Western; $5.15 to $5.80 for common to choice extra State; $5 to $5.75 for common to choice extra Western. *Rye Flour*, Quiet. *Wheat*, dull; receipts, 126,000 bush.; sales, 48,000 bush. at $1.07 to $1.09 for No. 2 Spring; $1.25 to $1.28 for winter red and amber western; $1.40 for white western. *Rye*, Dull; receipts 20,000 bush. *Corn*, Dull and lower; receipts, 59,000 bush.; sales, 41,000 bush. at 80c to 82c. *Barley*, Dull. *Oats*, Lower; receipts, 77,000 bush; sales, 29,000 bush. at 40c to 48c for Western; 47c to 51c for Ohio and State.

The Field.

Late Autumn Work.

The seeding of winter wheat, fall ploughing of stubbles and fallows, and gathering of the fruit and roots, having been properly attended to, there often remains a period of comparative leisure to the farmer during the latter part of autumn, which can be profitably employed in many ways.

THATCHING AND TRIMMING STACKS.—If this work is not done early in autumn, it should be at once proceeded with. It is a practice not followed in this country as much as it should be, and for want of it much of the outstanding crops, on farms where the barn room is insufficient, are seriously damaged by the late fall rains. Haystacks, especially, should be well thatched, otherwise several tons may be so much damaged by wet as to be practically worthless for fodder. It is a mistake often made to suppose that the cost of thatching is greater than the loss of what hay may become damaged by wet. There is no occasion for either expense being incurred or loss being suffered. Every farmer should learn and practice the art of thatching as part of the knowledge of his profession, and as being as great a necessity as to know how to perform any other operation on the farm. Thousands of stacks of hay are put up in the field where they are cut, in an easy, careless manner, and stand neglected till the winter is nearly over, when the hay comes out smelling with mould and dampness, and with half its value as fodder gone to the winds, simply from sheer carelessness. The stacks having been properly thatched, the next operation is to trim the sides all around so as to leave a close solid surface below the roof to the exposure of the weather. This can be done by using an old scythe blade, well sharpened, and fixed to a long straight handle. With this shave the sides of the stacks till they look smooth and solid, afterwards raking up and carrying to the barn or hayloft all the loose material shaved off. Stacks left unshaved often have a great quantity of loose stalks of hay hanging about them, which get soaked with and retain moisture after every storm, thus helping to injure the quality of the fodder for some distance into the stack.

Grain stacks seldom suffer from want of thatching, as besides being much more closely and neatly built than haystacks, they are usually threshed out as soon as the machine can be got to work, and the grain stored away in the barn, leaving only the straw to become a prey to the eccentricities of our changeable climate.

PASTURES AND MEADOWS.—These should not be allowed to be too closely fed down by stock, and as soon as they are shut up from them, the farmer should take his spade in hand and carefully go over them, breaking to pieces and scattering every little heap of cattle or horse-droppings he may see. If there is any fine well decomposed manure or compost to be had about the premises, it should be carefully scraped together, hauled out to the meadows, and scattered over the poorest spots as far as it will go. All bunches of grass that have been rejected by the stock should be cut with a sharp scythe, or bill-hook, and all roots of large perennial weeds dug out and carried to the compost heap.

DITCHES AND WATERCOURSES should all be cleared out before the heavy rains set in. Outlets must be made at such points in the meadows and fallows where the water is likely to accumulate and freeze up at the approach of winter into solid sheets of ice, should it find no means of egress. The cheapest and quickest way to do this is with the plough and scraper. In connection with this matter, we may ask if some one cannot invent a good, cheap, portable machine that will enable the work of scraping out the bulk of the earth from a ploughed ditch to be roughly, but cheaply done by horse-power, to be afterwards finished up neatly with the spade. The road scrapers in ordinary use are too wide for this purpose, where the saving of land is an object. Something that would neatly clean out the furrows at one operation in newly sown fields of grain, and yet leave no ridges of earth at the side, would also be desirable, and better than the plough for that purpose.

BARN-YARDS ought to be thoroughly cleaned out, and all the manure in them carried to the fields, either to be spread, or else composted in a large heap to be ready for application in spring. This done, the yard should be well covered with a good litter of straw; before the stock are turned into it to pass the winter season. Stables, byres, pig-styes and poultry-houses will be the better and healthier of a thorough washing and cleaning out, and a fumigation with burning sulphur to destroy insects, before the stock are to be housed in them for the winter.

FENCES should be put in good repair. This is easier and better done in the fall than during the busy and pushing season of spring. Begin with those that are in tolerable repair, needing only a few stones, a rail, or a board here and there; fix them up tight, and the stakes firm. Where rail fences are much out of repair and need re-laying, the work of pulling down the old fence and laying the bottom portion of it anew can be done now, and as soon as the first tolerable fall of snow enables a sleigh to run, the additional rails required can be drawn from the woods, the fence made to its full height, and if the ground be then frozen too hard to put in the stakes, they can be used to lock the corners, and so be ready on hand in spring as soon as the frost is out sufficiently to allow of stakes and riders being put on. On well managed farms, where the saving of land and keeping out weeds and briers from the fence corners is an object, straight fences, with the ends of the rails mortised into posts, or set between upright stakes, driven into the earth and tied together at the top with wire, on which the top rail rests, are much preferred to the ordinary zigzag style of the country, and as fewer rails are

SEP 7 1954 UNIVERSITY OF TORONTO

required in proportion to the length of the fence, they are cheapest in sections where rail timber is not plentiful.

Live Stock.—As the grass begins to fail, the cattle will need a little hay every day if it is desired to keep up their condition, and have them go into winter quarters full of thrift and health. The milch cows should be well looked after, and their flow of milk kept up as long as possible in the fall by artificial food, such as hay, cured corn fodder, cabbage and turnip leaves, bran mashes, &c. There is so much trouble and so little profit connected with winter butter-making, that unless a cow is an extra good milker during winter, or calves in the fall, many farmers prefer to dry all the cows off about Christmas, so that they may keep in fair condition on good hay through the winter, and be ready to come in full fleshed, with strong healthy calves, by the time spring returns, and the roots stored away are to be fed out to them. The calves of this season should be early attended to, and brought under shelter. They are too often left out till the last, and allowed to lose all their condition before they are noticed. Those who breed stock should remember that a constant state of thrift in the young growing animal is, next to good blood, of the first importance towards making good and profitable stock.

Sheep may remain out of the yards later than other stock, and being close and industrious grazers, will often keep up in condition till snow comes, especially when not too crowded on their pasture. They will pick out the corners of fences in stubbles and fallows, the borders of woodland, and eat much that other stock rejects. If improvement in the quality of the stock is desired, every faulty ewe should now be drafted out of the flock and sent to the butcher, or put up to be fed for Christmas mutton. Select to run with the flock the very best ram that your means will allow, and do not put him with the ewes too early, unless you have every facility and comfort in the way of food and buildings, for raising early lambs.

Swine.—The sows, and their fall litters of young pigs, should be well looked after, get comfortable warm quarters and abundance of food. Some cooked roots, such as potatoes, beets, or Swedes mashed up with some crushed corn or peas, will be good towards helping the sows to keep up their milk for the young ones, which should also get gradually accustomed to being fed by giving them, separate from the sow, what little milk or buttermilk can be spared from the house. There is nothing pays so well in pig breeding as keeping the stock in a state of constant health and growing thriftiness. Be particular to see that they have clean styes and abundance of clean dry litter to keep them warm. Fattening hogs had better be slaughtered and marketed as soon as they are well fatted. There is no profit in feeding beyond the point at which they will lay on fat in a fair proportion to the value of the food consumed. Extra fat hogs of great size are not now so much in favour with packers as they once were, nor is the price so much governed by size as formerly. Medium-sized hogs of 200 pounds, of the Suffolk, Essex, or Berkshire breed, ought to command better prices from ham and bacon curers than larger hogs of the old style land-pike, or of no particular breed, command from the pork-packers. Well-bred pigs always make the sweetest pork and most delicate ham and bacon, with a better admixture of fat and lean of fine quality than is found in common hogs.

Beet Root Sugar.

No. III.

EXTRACTING SUGAR FROM DRIED BEETS.

Another system which has been most extensively adopted in districts where the plantations of beet root were necessarily at considerable distances from the great sugar manufactory, and where fuel for the purposes of evaporation was scarce, has been the slicing and drying of the roots, followed by the extraction of the sugar by means of soaking the dried matter. To such an extent has this been carried, that in 1855 there was an enormous establishment in Gallicia, which in the growth and preparation of the roots, and the extraction of sugar from the dried slices, employed no less than 3,000 hands. This factory refined all the sugar that was grown within a circle of many miles in diameter. The roots were sliced and dried at fourteen different establishments located on the farm where the roots were grown, and not less than 1,200 people were employed in the cutting up and drying of the roots. By this method the liquor from the roots, macerated in a dry state, is found to contain fifty per cent. of sugar, and is free from a great many disturbing elements which are found to affect the actual juice of the root when produced from the recent bulbs. A great saving in fuel and trouble in evaporation is thus made, and the syrup produced is far purer than when the sugar is extracted at once from the recent roots. The manufacture of the sugar can go on at any season of the year, and the resulting pulp is equally good for cattle, and is obtained in far more convenient quantities.

This is one of the directions to which we must look for the small home manufacture of sugar and syrup, and the growth of demand for the root in Canada. This plan will suit many that a more elaborate one would not. The great majority of the farm population of the Continent of North America are used to the slicing and drying of apples, and other fruits; the slicing and drying of beet root is the same thing on a larger scale. One hundred pounds of beet root when sliced and dried weighs only eighteen pounds. This dried matter consists of nearly one-half sugar, and could therefore be carried from the farm to the sugar manufactory for a considerable distance, and if well prepared, would at the manufactory always command its full value, while the return teams could bring back a full load of compressed cake for use on the farm; thus the farmer willing to do so, could secure a far greator result in manure than his own crop would give. One ton of the dried roots would be equal to nearly six tons of green roots, so that it would bear carriage well.

The way the sliced and dried roots are treated for sugar is as follows: Several vessels are provided, and all are filled with the dried roots—the deeper the vessels are the better—water is poured on them so as just to cover the roots, making additions as the roots swell; the vessels are kept closely covered. As soon as the sliced matter is thoroughly softened, the contents of the vessel are drawn off and placed aside. The contents of the next are drawn off, and the liquor poured through the first, and this is repeated until the entire liquor has been through all the vessels. This plan takes up all the sugar in the least possible quantity of water, and the result ought to be a liquor containing about forty per cent. of sugar, which is then ready for evaporation into coarse syrup for the refinery, or it may be refined by the producer for his own use.

MAKING POTASH FROM FROM THE REFUSE.

In those manufactories where cattle feeding does not pay, or where the refuse from the pressed root cannot be sold, the refuse is burned in properly constructed furnaces, and yields an ash which contains a very large amount of potash, which is manufactured into the ordinary commercial article, and sold to the users of potash. It contains, however, a large proportion of salt, and although the ashes produce nearly one-half their weight in the mixture of potash and salt, yet if the salt is not taken out by chemical means, it must greatly deteriorate the value of the potash. A very large proportion of the potash used in France and Germany is produced from this source. This is, of course, a most dreadful waste for the land, and is only mentioned to show how the resulting matter can be utilized, where such utilization is necessary or advisable.

We have all long known that the leaves of the mangel crop when ploughed in make excellent manure for the following wheat, or other grain crop; the analysis of the ashes of the leaves shows the reason of this. The ashes of the leaf of the beet root contains fully fifty per cent. of a mixture of potash and salt. In the leaves of some kind of beet the potash predominates, in other kinds the salt forms the largest proportion; but all produce at this joint rate of the two substances.

No. IV.

PRACTICABILITY AND ADVANTAGES OF THE MANUFACTURE.

The writer does not mean for a moment to say that any one reading these articles can go into the manufacture from the information here given, and make good sugar. Such is not the intention of these papers. We want to draw the attention of the Canadian farmer to the great fact, that Canada, through the means of her agriculturists, can produce all the sugar required for the consumption of the Province, and that the doing so would put the proceeds into the pockets of the farmers, instead of, as now, being sent out of the country. The farmer wants another money-producing crop, and the proposed industry will give it to him. Too much cannot, therefore, be said in favour of such a project. Many will say, "Yes, it is like all new things, very well to talk about, but it won't answer;" and they may possibly refer to the disappointments lately inflicted on the farmer, and the public generally, by the attempted growth of flax on a large scale. Sugar is not like flax. The value of flax fibre is governed by the price of cotton, and the quantity used is also governed by the improvements in the manufacture of cotton goods; but for sugar no substitute has been found. Slave labour was at one time the governing power of the production of sugar, but slave labour has now happily ceased, and even if it had not, the French and Germans have shown that free-grown beet root sugar can compete with slave-grown cane sugar, and that the use of sugar is, within itself, the cause of a constantly increasing demand. No sooner does the price of sugar fall to a rate where it can compete with malt and grain in the manufacture of beer and spirits, than the demand for sugar is so increased, as at once to clear the market of all surplus supplies, and thus again restore the price to a remunerating point. In fact, the demand for sugar may be said to be practically unlimited, and as yet it has found no substitute to compete with it.

A friend of the writer, for whose opinion on these points he has a great respect, because the friend was bred up in the country, and on a Canadian farm, has rather thrown cold water on the proposed industry, because he says, "that the generality of farmers are not, and cannot be made, manufacturers;" that neither their means of information or habits of life tend in that direction, and that as a body they are incapable of dealing with a new industry like the one proposed.

Granting, (for argument's sake only, for I demur to the statement), that the general run of Canadian farmers have neither the intellect nor the means to manufacture sugar from beet root, there are none so ill-informed and stupid that they cannot cut the root up into slices, and dry it either in the open air, or in a kiln constructed for the purpose, and thus reduce the root to one-fifth of its bulk, so as to make it a profitable article to carry to the manufactory. But it will be said, "there are no manufactories." Granted again; but let farmers grow, and feed to their cattle, sugar beet, instead of mangels and turnips, and the manufactories will arise. Millions of capital are seeking investment, and a great industry, like the one proposed, would at once command a large proportion of it; but the capitalist cannot proceed until the sugar beet root is raised in plenty; whereas the farmer may as well raise the beet root as the mangel and turnip, and when he has done so, and thus shown the capitalist the fact that he can have any quantity of what he wants, manufactories will spring up like mushrooms, and we shall soon be exporters instead of importers of sugar.

The Canada Farmer is a temperance publication, and advocates neither the use nor the manufacture of spirits; but, notwithstanding that, people will have fermented liquors and spirits, and all the rough grain produced by the farmer is not sufficient to make what is required; hence, millions of bushels of Indian corn are annually imported from the States, to the great loss of our farmers, who, in producing sugar beet, would produce a substitute for the corn now brought in, and the dried beet would not be a more cumbrous article to carry to market for the distiller's purpose than barley now is, and would produce a greater price per acre for the land sown, with this advantage too, that if the results of the root are applied to the land as manure, an improvement, instead of a deterioration, in producing properties, is found; whereas, grain growing occasions a serious diminution in the producing power of a farm.

NO. 5.

HOME PRODUCTION.

Since this series of articles was commenced we have ascertained that the same views have been adopted in Europe. The sugar manufacturers find that the business is now well established, and the demand so enormous for the beet root sugar, that the practice of growing the roots and manufacturing the sugar as one business is not the most profitable mode of procedure. The roots are so bulky that they will not bear carriage far; the business of growing them and of making the most of them when grown is more the business of the farmer than the manufacturer; and the course of affairs now tends to the manufacture of the crude syrup or sugar directly on the farm, and the subsequent conversion of it into refined sugar at the manufactory.

For the purpose of carrying out these views, a system has been devised whereby the farmer can, on a small scale, bring the produce of the beet root into a state fit for the refinery. The author of this plan is M. Kissel. We have sent for his publications, and all others which bear on the point of the home manufacture of the syrup, the results of which shall in due time be made known to our readers. It is possible, however, that the present war may interfere with our intentions.

Meantime, there is another and most important phase of the subject which calls for special attention, and that is the fact that the cultivation of the sugar beet, when the results of the pulp of the root and the leaves of the plant are returned to the soil, cause a considerable and constant increase of fertility, until, from the statistics of the countries in which beet root sugar is manufactured, it is now found that the increase in the growth of wheat and other cereals is exactly in equal proportion with the increase of the root. Wheat, however, makes the best alternating crop.

This is not only proved by the statistics of the country in which beet root sugar is principally made, but the fact has long since been shown that by the growth of the beet, owing to the manure necessarily applied to produce the crop, and owing to the destruction of weeds which the tillage of the plant calls for, the land used for the purpose is increasing in richness and freedom from weeds, until a far higher grade of fertility is established than existed before the root was grown.

Land does not, under proper cultivation, get "sick" of beet root, as it does of other crops. The same fields have produced heavy and increasing crops of beet root year after year for very lengthened periods. In the beet root sugar countries, the same fields are used for that crop year after year without injury. The hauling of the roots to the factory is so heavy an item, that it makes it well worth the while of the manufacturer (who is also the grower of the root) to prefer what was at one time supposed to be the chance of injury to the land by repeated cropping, to the absolute expense of hauling the root from a distance; but this supposed injury by continual cropping with beet is now found to be a fallacy; the more beets are grown, provided the refuse is returned to the land, the better the land for crops both of beets and of wheat.

BEET ROOT AS A DESTROYER OF WEEDS.

This is another great argument in favour of the growth of the root in Canada; it would be the most destructive course of cropping for weeds that could be imagined. Thus, beets being a hoed crop, would leave the land clean for spring wheat the following year; but what would be better culture for Canada would be beets, followed by a partial summer fallow, then fall wheat. The stubbles of the fall wheat being immediately ploughed and manured, would leave the land in the finest possible condition for beets again, and this course would destroy, with the greatest amount of cropping and the

least amount of labour, every class of weed most dreaded by the Canadian farmer.

Any other grain crop could be grown instead of wheat where it was found advisable, and other crops could be interpolated if required; but the rotation of beet and grain crops really gives the land the benefit not only of the manure resulting from the refuse of both these crops in the barnyard, but the additional advantage of a green crop ploughed in, for the leaves of a beet crop are fully equal to the benefit to be derived from the destruction and ploughing in of a crop of clover.

One will naturally say, however, that the beet crop as food for cattle is deteriorated by the extraction of the sugar. This does not appear to be the case. The sugar, when extracted from the crop of either beets or mangels, does not seem to be missed by the cattle; they really do better on the refuse without the sugar than with it, and those who have observed the scouring effect of beets when fed to cattle, pigs, or sheep, in an entire state, will understand that the sugar seems to be too rich for the stomachs of the animals.

IMPORTANCE OF KEEPING UP THE BEST VARIETIES.

Another great point which calls for the popularization of the growth of beet root and the manufacture of the sugar on the farm, is the improvement in the *quality* of the root, more particularly in its increased production of sugar, and decreased production of mischievous elements, such as salt, &c. If the beet root sugar were manufactured by the people, we should have hundreds of thousands of intelligent people watching for and knowing of the results obtained from the different varieties of the root. The beet is biennial, and raised from seed, and, like all other plants so raised, is subject to great alterations both in size and quality. It naturally runs into varieties, and what the gardeners call "sports," many of which are either better or worse than the original stock. This is not the case with potatoes, or other plants or trees propagated by cuttings, but all plants produced from seed vary from year to year. If, as we said before, the manufacture of sugar were a pursuit of the people, each grower would keep close watch on his fields for special varieties, and where he found them, would propagate that variety.

The great manufacturer cannot do this. His time is too valuable, and his attention too much engaged with other matters to keep a close watch on the results of special roots, although he looks out sharp enough that his general average of sugar keeps up to the mark.

Not only is it a great object to get the varieties of root with the most sugar in them, but also those that contain the least salt, and until the discovery took place of the properties of the parchment paper diaphragms, which would separate the salt from the sugar, as mentioned in a previous article, the presence of salt in too large quantities was a fatal fault.

By popular observation these and other qualities are kept close watch on. Improvements are made, and faults avoided in a hundredfold greater degree than when the manufacture and growth were carried on on a gigantic scale.

Very much has been done in this respect already, even under the present management, and where observation is necessarily limited to comparatively few points. When the manufacture of beet root sugar was commenced in France, six per cent. was a great average to obtain, and often less was the result of all that skill and capital could be brought to effect. Now, twelve per cent. of sugar is an everyday occurrence, and large factories average on their year's work ten per cent.

Great improvement has also taken place in the quantity of roots raised per acre, as well as in the richness of the individual roots in sugar. Ten tons per acre of roots was considered a large crop; now, no grower is satisfied with less than double that amount. This increase of bulk will, of course, in a great measure, account for increase of yield in the sugar, but not altogether so, for experiment and chemical analysis has shown, year after year, that varieties of the roots may be found which increase in richness of sugar, as well as in size and yield per acre, and that in a far greater degree than was originally supposed possible.

Another great point has latterly been obtained, namely, the preservation of the pulp resulting from the beet root sugar manufacture. Originally, sufficient cattle had to be kept to consume the pulp in a recent state as fast as it was produced. Now, they preserve the pulp and the pulp cakes for one and even two full years, without difficulty or injury to its feeding qualities. The advantages of this course are too apparent to require comment.

A Backwoods Farm.

LIVING IN A SHANTY.

Our first day's work on the new farm was on the 21st day of November, 1859, and during a heavy gale of snow. We had previously hired a yoke of oxen, and a squatter had formerly chopped a small portion of the land.

We lived in a neighbour's shanty, or rather small log house, but we found boarding out would soon exhaust our small cash means, and besides, the want of our own household arrangements greatly impeded our work; so on the 30th day of the above month we commenced to build a regular lumberer's shanty.

There was no fireplace in it, but the fire was lit in the centre of the single room, and bed-places or berths were formed all round by boring auger-holes into the logs, and driving pins about four feet long into them, supported at the free end by poles at right angles; boards laid on these pins, and straw mattresses on the boards, completed our dwelling; and when the wind did not blow the smoke about, but allowed it to ascend quietly through the hole in the roof, there really was quite an air of comfort about the house, especially on stormy evenings, when the contrast between the cosy interior and the dreary scene without tended much to gild our shanty with some of the attributes of home. No woman had as yet been brought on the farm, and for a cook, a young Prussian or Dutch boy had been "caught," and installed in that office. His efforts were not very successful at first, but as they were principally directed to boiling pork and potatoes, and baking shanty cake, his failures were not so very apparent. It is true that we could not induce the young untutored to wash our plates very carefully, but as the light that enlightened our shanty all came down the chimney, or hole left for the smoke, we could not so distinctly detect the deficiencies of the scullery operations.

Time went on as the chopping progressed, and we became somewhat fastidious in our food. We must have sweetcake and shortbread, and dried apple pies—and here failure stared our Dutch cook in the face. However, he improved about as fast in the culinary art as our tastes became more fastidious, and to this day (for he lives with us now, a grown man, but never since a cook) we often laugh at former failures in cooking.

We had some ludicrous episodes, and some accidents during the winter whilst chopping. Amongst others, there was a sort of play or trick that old bush hands are fond of playing off on the greener and more recent visitors. Of course, stories of wild animals and adventures, in the long winter evenings, were the order of the time; and these were especially indulged in when, as it often happened, some intending settlers called in to ask the particulars of locations, and to stop all night out of the storm. Then the fun commenced. After some wonderful stories of wild beasts had been told, and corresponding relations of prowess given, and just when all the new comers were breathless with expectation and excitement, an unearthly noise was heard outside—something between a roar, a scream, and a bark. All started to their feet, especially the emigrant visitors, and rushed out of doors—these last gentry, however, nervously following in the rear.

The noise was perfectly well known to the initiated to be produced by a piece of thin maple wood, about six inches long, and attached to a piece of deerskin, tied to a pliant springy handle, about four feet long. When this instrument is properly made, and whirled round and round the head, it gives out a most unearthly sound, of wonderful modulation, according to the skill used, and one that may well frighten any new comer in the woods, especially one who had been well prepared beforehand from some such source as story-telling. Two or three of our men were provided with these machines, and were running hither and thither—of course out of sight—in the storm, whilst the uninitiated rushed after them with all sorts of weapons, urged on by those in advance to come quickly. The roars would be first on one side and then on another, as the wild animals were supposed to be flying before their pursuers—and many were the tumbles and rolls the visitors got in the deep snow, or over stumps and logs, while endeavouring to overtake or avoid the supposed wild beast. At last it was generally the case that some one discovered the trick, and, of course, all returned to the shanty laughing and joking the new-comers on the strange noises to be heard in Canadian back-woods, and holding great investigations over barked shins and broken or bleeding noses.

CHOPPING THE LAND.

The winter of 1860-1 was very severe; the snow lay nearly four feet deep on the level, and was solid and hard; and as we were too late in beginning to get underbrushing done, as it ought to have been, before the snow fell, we were compelled to chop away at the trees and leave the underbrushing until the following spring. This, of course, was bad management, but we could not control the elements, and therefore had to do the best we could.

We chopped that winter 120 acres of land, having hired four choppers in addition to our own strength—active, wiry little Frenchmen they were, and beautiful choppers—no better men exist, as adapted for such work, than the Lower Canadian Frenchmen. Always gay and merry, and never discontented, all they want is pork and potatoes, tea and some sweetcake shortened with pork fat (provided they are dressed by a decent cook), and a gay Frenchman will willingly go for nine months or more far into uninhabited wilds, and only look forward to returning amongst his fellow men once a year for about a month. The wonder is how such small men can chop so much, and such large trees; and many times in after years I have noticed such and such trees as having been chopped by Ba'tist or Jean. Those stumps that winter were often left six feet high, so deep was the snow when they were chopped. About this time one of our oxen was missed, and a search was instituted in all directions, but without effect. He was seen only an hour before being missed, and no track could be found where he had left the chopping. We made a circuit round our camp in the deep snow, and thought it certain by that means to find his path of exit, but to no purpose, and after a fruitless search we gave it up, wondering how it was possible that he could have got away. When the spring opened, and the snow melted, our doubts were ended. Within twenty rods of our shanty the ox had fallen, having caught his hind foot in the fork of a fallen tree, the wood of which was not more than about four inches in diameter. The foot was held fast, and the poor brute was starved and frozen to death almost close to the house. In his struggles for freedom he had chafed all the flesh from the bone.

Spring set in that year very early, and remarkably dry, during the month of May; and about the first of April we turned all hands on to cutting underbrush, wherever it was possible to get at it. The whole chopping was gone over, and all the small stuff chopped, and on the 25th of May, 1860, we set fire to the new fallow.

BURNING BRUSH.

On the 25th day of May, the day we had determined to fire the brush, we all prepared touchwood and pine slips, with matches, and every small combustible material we could obtain. The great art is to fire the whole at once, and to select a dry, hot day and "half a gale" of wind. Such a wind and such a day we had, and about 10 o'clock, when the dew was all off—a very important point—and everything hot and dry, we commenced to set fire. We passed at intervals of about fifty feet all down the windward side of the chopping, and built little fires. All were engaged at once, in order to have as tremendous a fire as possible. In about half an hour the flames began to gather strength, and truly it was a grand sight. The wood, leaves, and decayed stumps here and there being all dry, caught like touch-paper, and the wind being very high, in an inconceivably short time the whole fallow was one mass of flames fully fifty feet high, roaring like some furious volcano, and sweeping all before it. We had no neighbours, and we knew the fire would not run in the neighbouring green woods so early in the year, so we allowed the flames to have their own course and full sweep, and by evening the finest and best burn I ever saw was the consequence. All the brush was completely burned, and much of the small timber. Where the windrows of the tops were all thrown together—sometimes two hundred yards long, a solid mass of brushwood—a lane of twelve to twenty feet wide was entirely burnt up, so much so that we could and did drive waggons over and through the new fallow to collect the ashes for potash making.

This burn was of immense value to us. About one-half the timber and all the small stuff was entirely destroyed, burnt, and completely cleared away, leaving only heaps on heaps of ashes. The art of chopping land to advantage consists entirely in arranging your windrows in this manner: You first throw down some great unmanageable tree—probably an elm—and carefully chop down all the branches, causing them to lie as smoothly as possible, so as to have the brush-heap solid at the bottom. You next throw into and on to this heap all the adjoining timber, at various angles, just as they incline or otherwise towards the pile in question. Practice will enable a good chopper to do this in a wonderful manner, especially when he takes into consideration the direction of the prevailing heavy winds of the district—a very important point. Of course, in this direction the windrow must be made, and a very little inclination of the tree-top will cause the tree to go where it is wanted. If, as sometimes happens, an obstinate tree will persist in going the wrong way, and will fall away from the heap, instead of on it, it is of little consequence, as this will be in the next row, parallel, or thereabout, to the first.

I have seen, on our land, fallows so well chopped, and the trees so adroitly thrown on each other, that you could have—and I have many times—walked for a hundred yards, without stepping off this immense long brush-heap. Some of our men could never attain the art, while others could do pretty much as they chose with the trees. In chopping and clearing land, all you want to lighten your job one half is, in addition to good chopping, a perfectly dry time and a strong wind; and you had better wait a month or two in the spring than attempt to burn until these conditions occur. Then your work for the rest of the job is light in comparison to being without such a burn. If, on the other hand, as it often happens, you try to burn some ill-piled brush-heaps, with trees thrown every way, and the fire just runs through without consuming the brushwood, your labour is trebled at least, for the fire never runs a second time, and it is "pick and pile" brushwood and chips for weeks and months, until you are sick of it.

This happened to us in the next hundred acres we had chopped, and it cost us $9 an acre to log it, as will be related in its proper place. Of course, we gradually acquired experience, but at first we should have miserably failed but for the counsel and help of a friend of ours who visited our shanty the first winter.

CLEARING LAND—GRUBBING THE TREES.

Amongst other trials to clear land to better advantage, that of grubbing the trees once occurred to us as not only practicable, but advisable. We reasoned thus—that the stumps were a greater impediment than the roots—that if the tree could be grubbed out at once, using the tree itself as a lever to tear up any roots that might be difficult to cut off, the land would be more easily worked. We accordingly laid out two acres as a trial piece, carefully keeping an account of the time. We did not find it a successful experiment. The time it required was too great. Five trees could be cut down while one was being grubbed out. Certainly, when finished, the land looked almost

like old land—no stumps anywhere, but when you attempted to plough there was scarcely any improvement over the ordinary difficulties of working new land; and this land to this day is not more easily worked than stumpy land, so far as roots are concerned. True, the stumps are certainly not there, but the roots are not more decayed than those attached to the stumps. In fact, from some cause, I do not think they are as much so, and this point has often been a matter of wonderment and a scource of much thought.

I have a theory, that the decay of stumps is to a great extent due to a perpetual attempt of the sap to continue to perform its regular functions at its appointed season, and the natural evaporation from the drying up of that part exposed to the air furnishes a certain demand. The roots, having no such demand from grubbed stumps, do not therefore become alternately wet and dry, as others ordinarily chopped do, but remain always wet. This opinion is strongly supported by the condition of some stumps under a sheep shed, that I examined and dug out a short time since. They had been covered up with manure, and all but the very top was thus kept quite wet, and had been so during nearly ten years that had elapsed since they were chopped. The top that protruded above the manure was quite decayed, but the roots were absolutely green—yes, quite green. I showed many of the smaller fibrous roots to some intelligent people who happened to be present, who were equally surprised with myself. There was no sprout whatever, nor ever had been, from this stump, as the shed was built in 1861, one year after the land was chopped, so there was time enough for decay to have affected the roots, unless some preservative action had been going on, attributed to the moisture of the manure. The kind of timber was 13-inch basswood and beech.

We cleared out our farm-yard last year, in a part that had been uncleaned for eight years, and found the stumps, so far as the roots were concerned, quite decayed, and easily jerked out by the oxen, but these had been exposed to wet and dry, sun and air, and consequently to a continual ascent and descent of sap, which probably accounts for the difference.

I had a visit the other day from a friend of more theoretical than practical knowledge, and he actually was about going on new land with the full conviction that trees can be grubbed out, and the land thus cleared, and that the advantages of this course would far overbalance the cost. Of course, I used all my experience in persuading him to think twice before doing anything of the kind, and at all events to try one acre before buying a tract of five hundred or six hundred acres with the certain conviction in his own mind that it would succeed much better than the old plan. He, however, was so bent on his own plan of operations that he left me to look at the tract in question.

BURNING AND BRANDING.

We now came to the blackest job of all, but at the same time, one which I always took great delight in, namely, the firing log-heaps. The art consists in first having a good, well and closely piled log-heap, and next in having a good breeze of wind to assist the combustion. The end of the heap is the best part to light first, provided the wind suits, as the fire more readily gets a thorough hold. The attendance on the heaps must be continued into the night, otherwise there will be some that spread out whilst burning, and then do not consume so well.

I always found more difficulty in leaving the fallow when fully alight than the wish for rest could overcome. It seemed such a pity not to keep punching away first at one heap, then at another, as the attendance thereby given so much improved the fire—and then a succession of such jolly bonfires—and I always did love a bonfire—and these were such good ones—so it always ended in my working out in the fallow, literally enjoying it, often after ten o'clock at night; and next morning, when the sun rose, and all the heaps were partly burned, and looked almost out, I almost regretted leaving them at all. However, after branding up and again punching in the outside logs, they were soon all smoking again; but the effect of the fires is for less exhilarating by day than by night. With us, we had such a quantity on fire, that I determined not to follow this course again, but to log for about three days, and if the weather proved dry, to burn and brand up this piece before firing any more. This plan gives more time to collect ashes, which, of course, must remain ungathered as long as the heaps are burning. We sometimes raked them as fast as the heaps consumed, but it took a great deal of time, and when we came to carry them there was usually fire remaining in them, which endangered the waggon box. So, on the whole, we found it better to deal with about five acres at a time, and by using hand-barrows to carry the ashes into heaps of sufficient size to make a waggon-load in a place.

We logged in this way all the summer of 1861, and our one yoke of oxen did the whole of it, and without accident, except to one which strained his foot, which laid him up for a few days; and the other was sick a while from being overfed with ground grain. A quart of melted lard poured down his throat soon restored him, and he continued to log steadily until the frost came. Of course, we drew aside the rail-cuts for fencing as we progressed, but in this respect we were careless and improvident. We thought twenty to twenty-five acre fields would be small enough for so large a farm, but it was a great mistake; they ought not to have exceeded ten or twelve acres each. And, when we found too late the inconvenience of such large fields, we also found that the rail timber from which to construct the fences to make the fields smaller was all burnt up, and we suffer from the neglect to this day. We certainly saved some first cost, as twenty-five acres do not require nearly so many rails as two twelve and a half acre fields, but it was a serious mistake notwithstanding.

Another was, we did not make "worm" enough to any of our fences. We thought to make the rails go as far as possible, consequently, the fine rails, being all hardwood, were during rainy weather as slippery as eels, and the least wind would level rods on rods of them. In fact, it was hardly possible to get over one of these unstaked and unrider ed fences in wet weather without throwing down several rails.

Another error was, we did not attend sufficiently to the entire burning up of the large swamp timber, such as elm, basswood, and hemlock. Many of these were ultimately left, and when the smaller timber was consumed, there was nothing to burn them up with, and they continued to cumber the fields until some stumps were ready to come out, when we succeeded in consuming these old stumbling-blocks.

Another evil is, to run over the swamp-holes and frog-ponds, leaving the fallen timber in them. We had better far have hauled it out while we were at it, and made all clean, than allow them to remain unburnt. In the one case we have productive pasture land, which can be cut for hay, and often produces the heaviest crops, whilst in the other, we have a pestilent mess, that remains year after year until grown up to willows and sedge, affording no food for cattle, and proving a regular breeding place for mosquitoes.

C.

Silver Beet as a Manure Plant.

I noticed in a recent number of The Weekly Globe an account of the growth of a plant called Silver Beet, and a recommendation to plough it under as manure. I at once procured some seed to test the rapidity of its growth, and, as advised, I soaked it in warm water twenty-four hours, and sowed it in drills two feet apart, scattering the seeds along the drill at about three inches from seed to seed.

As the weather was very hot and dry, and I feared the seed might not come up, the sowing was delayed until the 18th of June, which I considered very late; the ground, however, was good, and the sowing was made immediately after the heavy rains we had at that time. The depth at which the seeds were buried was about two inches—not more—as I was advised to be most particular in that respect. The seeds did not come up very regularly, but were somewhat delayed in their germination by the hot dry weather.

It was therefore the first day of July before the plants could be seen in rows. They were hoed once, and now (Aug. 13th) they entirely cover the ground, and are twenty inches high; nothing is visible but a mass of green leaves—no doubt entirely calculated as a green crop for ploughing under. I am quite convinced that such a quantity of green leaves and fibrous roots ploughed under would afford an immense mass of the very best manure. There would not be any serious difficulty in ploughing them under although so much in quantity, as a furrow drawn deeper than usual between the rows would form a trench quite sufficient to receive the mass of green stuff, and the one following would entirely cover it all in.

Chemical analysis shows the leaves of all the beet tribe to possess the power of extracting large quantities of potash from the soil, and when in its turn it is again returned to the earth in a form that the following crop can at once assimilate, a most excellent yield may safely be relied on.

There is one great advantage in growing the Silver Beet over many others, as no fly or worm has yet shown any inclination to attack it, and the young and tender plant is allowed to grow in peace. When we come to consider that about six weeks have sufficed for the growth of a mass of green stuff, so abundant that there is some difficulty in burying it, we can hardly over-estimate the advantage it is likely to possess as a green manure crop.

In raising seed for another year, nothing more is required than to take up a few of the roots in the fall, and keep them in a dry place, or packed in dry sand quite free from frost, and plant again about the latter end of April, when a most abundant crop of seed will be the result. For many years in England I was accustomed to grow mangels as a crop to precede wheat, and although we rarely succeeded in getting the wheat sown, (after the removal of the mangels), before the very last of October, and sometimes the beginning of November, we never failed in having forty bushels of good wheat per acre. The great crop was entirely attributed to the mangel leaves being ploughed under at wheat sowing; the land was, however, of good quality. No leaves were allowed to be eaten by cattle, and thus carried off the land. All were ploughed well under after the removal of the roots. I find the roots are fibrous, not bulbs as in mangels, and are consequently not fit for food.

C.

The *Michigan Farmer* says the economy of hay caps has been demonstrated at the Michigan Agricultural College Farm this season. They are made of cotton, are four and a half feet square. Even when there was no rain it was found that hay cured under them was superior in quality to that exposed to the light and sun. They are also used on wheat.

Barn-yard Manure.

To the farmer there is no manure so valuable for general use as that made in the barn-yard, because such contains every kind of plant food which has during the previous year been removed from the soil. There is no form of investing money so profitable to him, both in the quickness of return, and the high rate of interest received, as that upon manure. It is certain that the constant application of manure will directly double his returns from his land, and the benefits of such application will be carried on from year to year, in the superior richness of that portion of each crop which will again and again be used for the nourishment of his fields.

Let the farmer beware how he runs into debt to the grocer and the tailor, how he invests his hard-earned means in shares and stocks, but he need never be afraid even to become indebted for manure. Returns from such an investment are rapid, and the rate of interest high. Let us loan our money thus to nature, and she will repay us with generosity and without fail.

The principle that the best manure is that made under cover is now generally endorsed by the most intelligent of our farmers—indeed, of agriculturists all over the civilized world.

The following table, being the result of experiments made in England, giving the composition in pounds weight of a heap of manure at four different periods, will convey to the reader an idea of the changes which took place in the composition of manure from exposure :—

	Put up November 3rd.	After 5 months April 3rd.	After 9 months August 29th.	After 12 months November 15th.
Weight of manures in lbs.	2838	2026	1994	1974
Water	1877.9	1336 1	1505.3	1466.5
Dry matter....	960.1	689.9	488.7	507.5
Soluble organic matters..	70.38	86.51	58.83	54.04
Soluble inorganic matters..	43.71	57.88	39 16	36.89
Insoluble organic matters	781.07	389.74	243.22	214 92
Insoluble inorganic matters	114.94	155.77	147.49	201.65
Total nitrogen	18.23	18.14	13.14	13.03
Equal to ammonia	22.14	22.02	15.96	15 75

I have heard many farmers speak of the fear they had of giving their land too much barn-yard manure. No doubt, this is an error that may be committed, but from my experience, I cannot say that the fault of the Canadian farmer is often that of overfeeding, either to his land or to his stock.

I have often seen crops of wheat heavy in the straw, but light in the head, and I have in most cases traced the deficiency in the fulness of grain to the general fault of inferior seed, without perceiving that the abundance of straw was any greater than should be borne by a fair crop of wheat.

The feeding of cattle upon the farm, therefore, makes the most useful of manure, for the solid and liquid excrements that are sopped up by straw, &c., contain all those fertilizing elements that have been extracted from the actual plant, and that are in a state in which they may be returned with maximum advantage to the growing crops.

A most important point in the case of barn-yard manure is the prevention, as far as possible, of the transmission of noxious weeds to the field.

It is a great mistake to throw seeds away *by themselves*, for the birds pick them up, and again distribute them over the fields.

The manure heap may be made a means of destroying such weeds.

Let seeds be thrown in with the manure in such a manner that when the piles are made the seeds shall be well covered, the heat of manure heaps will destroy the germinating power of nearly all, and if any seeds do escape death by this process, after growing in the richness of manure they are weak and spindling, and far more easily killed than such as have been carried directly to the fields by birds.

The richer the food, the richer the manures, and this should be carefully considered in applying to different crops or to different soils.

Manure is to land what food is to the animal, and the application should be carefully regulated to suit the requirements of land under many different circumstances.

The subject of intermixing clay, peat, and such substances, with barn-yard manures, has been so well handled in your columns of late, that it would be superfluous to revive the subject. I would only say that a succession of layers of clay and a coating of clay outside the manure heap, act very beneficially, not only in preventing the escape of valuable gases, but also of that heat which will accelerate the necessary chemical combinations, will destroy the germinating power of many noxious weeds, and will hasten the reduction of the manure to that state in which it will most readily be taken up by the land to which it shall be applied.

C. E. W.

From South Australia the accounts of the crops are very favourable. The principle of a great measure of land reform has also been settled, which permits land at £1 per acre being paid for in yearly instalments of 2s. each, with favourable conditions of settlement, cultivation, and improvement. This measure is regarded as most favourable to the future interests of South Australia, placing it in a position to attract settlers equally with the other colonies.

Sowing Timothy in Autumn.

Thore is quite a scarcity of timothy seed this year for next year's sowing, especially in the States, consequently those who have been able to gather any will probably obtain double the price it usually sells for. But the worst of it is that many fields seeded last spring failed to take, from the want of moisture shortly after seeding time. The same may be said of clover. This could easily have been avoided where the seeding down to grass is to be done on winter wheat, by sowing the timothy seed in the fall. There is much more certainty of getting a good catch with timothy, and also orchard grass, when it is sown in the autumn, than there is in the spring seeding. Timothy is perfectly hardy, and the young plants can stand the winter as well as winter wheat. Should a spring or early summer drought occur, the plants will be well rooted, and have a sufficient hold of the soil to push forward early and rapidly, and are then much less likely to be scorched out. Clover cannot well be sown in autumn here, but if the land has been fall sown with timothy, and it is desired to have an admixture of clover in the meadow, the clover, if sown early in spring, will take better from the slight mulching it will obtain from the young timothy plants, than if it had no protection from the hot sun in May and June.

Wheat Midge in England.

To the Editor.

Sir,—The fears entertained in England of the appearance of that scourge of which we have had so fatal an experience, are, I fear, but too well founded. In the latter end of July I was asked by a farmer in Gloucestershire to examine his wheat, which had assumed a sickly colour and shrivelled form On examination I found the midge (*Cecydomia tritici*) very generally spread over the field. It is to be hoped that, should this pest become such a scourge as it has been in America, the farmers of old England will take a lesson from our young experience, and treat the midge to a general dose of coarse wheat.

C. E. W.

Ancaster, Sept. 3rd, 1870.

Insect Depredations.—If I were to estimate the average loss per annum of the farmers of this country from insects at one hundred millions of dollars, I should doubtless be far below the mark. The loss of fruit alone by the devastations of insects, within a radius of fifty miles from this city, must amount in value to millions. In my neighbourhood the peach once flourished, but flourishes no more, and cherries have been all but annihilated. Apples were till lately our most profitable and perhaps our most important product, but the worms take half our average crop, and sadly damage what they do not utterly destroy. Plums we have ceased to grow or expect; our pears are generally stung and often blighted; even the currant has at last its fruit-destroying worm. We must fight our paltry adversaries more efficiently, or allow them to drive us wholly from the field.—*Horace Greeley.*

Stock Department.

Housing Stock in Winter.

There can be no question that in such a rigorous and changeable climate as ours, shelter for stock during six months of the year, from the 1st November to the 1st May, is absolutely essential to insure their thrift and healthiness.

In arranging the yards and buildings, however, to that end, there are some important points that seem to be too generally overlooked by our farmers. One of these is the dividing and locating them so as to arrange that the different classes of stock do not intermix, to the injury of one another. If horses are bred on the farm, the colts need a good yard for exercise, with comfortable close sheds fitted with feeding racks, to run into at nights and stormy days. The young cattle need a separate yard and sheds with racks to themselves, where they will have room to move about, and not be kept in continual fear of the old cows and oxen, which should be kept separately in their stalls. Sheep should never be among other stock, but have large yards with good sheds open to the south, if open at all. In any case, buildings that are used for young stock or sheep must be constructed as to allow of good ventilation at all times when necessary.

Another point often neglected is the supplying light to animals that are kept in close confinement most of the time. We have frequently observed that horses kept in dark stables are always more subject to shying when they are driven out, than those that have well lighted stables. One can easily conceive that a horse brought out from a dark stable into the bright glare of a winter sunshine is partially blinded, and, in fact, we believe much of the blindness common among horses is caused by constant sudden exposure to light every time they are taken out of their stables. Nature has given light as one of her blessings conducive to health, all creatures having the organ of sight largely developed, and to deprive any of them of the means of exercising that faculty is sure to result disastrously in some form or other. It is noticeable how much less shying there is among horses in the summer than in winter, which is probably due to their being more out of their stables during that season, and even when in their stalls, the doors are left open during the day time.

Still another point is that of constant cleanliness, both inside and out of their shelters. We believe much of the diseases prevalent amongst stock in winter can be traced to the want of cleanliness and pure air. Every yard and shed should be kept well covered with clean straw, and every stable and byre so arranged that the stalls and floors can be readily cleaned out, and the animals kept from accumulating filth on their bodies. What else could be expected than a general unhealthiness and want of thrift in animals, that are living in an atmosphere that is constantly impregnated with bad odours and impurities. Let the stables and byres be well dried during the day, when it is not excessively cold or blowing snow drifts, by leaving doors and windows open for several hours. In the case of animals being fed up for the butcher, it may not be objectionable to keep them in partial darkness, in order to induce them to lie down and keep in a state of rest as much as possible; but with all others there should be a good supply of light allowed during the greater portion of the day, and if the cows can be turned out of their byres by themselves, for a few hours each fine day, they will enjoy better health.

Lastly, we too often see that the amount of space allowed for winter quarters to stock is altogether too small for their comfort; yard room, especially, is often very much cramped and confined, as if the land on a farm was of as great value as that in a city. It is better to have yards of good size, and, after clearing them of the winter's accumulation of manure in spring, plant them with cabbages, beets, mangels, or carrots, reserving only the stable yard for summer use.

The amount of stall room allowed is also often far too small, and the animals are crowded together in such a manner as to make them feel anything but comfortable. The idea of carpenters and builders, who generally put up the stalls, seems to be to make them all of one uniform size, the dimensions of which are dictated by some arbitrary rule or caprice, whatever it may be called. They do not seem to think the size of the stalls should vary, so as to accomodate different sized animals, but that, like the bed of Procrustes, the same space should fit all comers. It seems to be overlooked that the stalls or spaces set apart for each beast may just as well be either all of such a size as to accommodate comfortably the largest ox, or be graduated in size in order to economize space, and yet each give comfortable space for the animal to occupy it, according as it is large or small. The more ease and comfort the stock can obtain when tied up in their stalls, the more contented they will be, and the better they will thrive.

Mr. Duncan's Stock Sale.—An extensive sale of valuable animals, chiefly Shorthorns, took place recently at Towanda, Illinois, on the farm of Mr. Duncan. The sale, says the *Prairie Farmer*, attracted one of the largest assemblages that has ever been gathered on a similar occasion in the West. Ten bulls were sold, including the celebrated sire of the herd, Minister, (a portrait of whom appeared in the Cadada Farmer), who was purchased by Mr. Wilson, of Kansas, for the sum of $1,760. The other bulls fetched sums varying from $370 to $700. One cow sold for $1,500; two others for over $1,000, and the remainder at prices from $100 to $700. The total sum realized for twenty-seven head was $15,500. A fine lot of hogs were also sold, and brought from $60 to $187 per head.

Mellendean Leicesters.

We have repeatedly given a short account of the annual sale of rams at Kelso; and in another column will be found a brief notice of the last, which took place on the 9th of September. This sale, from small beginnings, has attained to the most important place of ram sales in Scotland.

Prominent amongst the competitors at this sale for the past thirty years have been the Mellendean Leicesters, being part of a breed of sheep which are somewhat of a distinct type, now called "Border Leicesters," for which the neighbourhood of Kelso and the valley of the Tweed have long been famous, and of which our engraving, from a photograph by Gray, gives two very beautiful specimens. The Mellendean flock was owned by the late Thomas Stark, who had a keen eye for fine shapely animals, and whose flock, from the small foundation of ten good breeding ewes, has gradually progressed through every stage of improvement up to its present state.

MELLENDEAN LEICESTER RAMS.

At the sale at Kelso, on the 10th September, 1869, the Mellendean sheep, forty in number, brought the highest average of 1751 offered, that average being £16 9s. 4d. sterling, and one sheep bringing £109 sterling. The average of the Mellendean sheep for the year 1868 was about £7 above 1869, when the total number at sale was also larger than in 1869. At the Kelso sale competition amongst breeders is very keen, and it requires all that science, skill, and a liberal expenditure can do to keep pace with others, or retain the prominence already gained. In these respects the Mellendean sheep are well looked after. Some of their leading features are their lustrous fine curly wool, so much in request by manufacturers of the finest woollen fabrics, their soft and mellow handling, which bespeaks them kindly feeders, pure white heads and sprightly eyes, well-set ears and strong muscular necks, splendid breasts, clean short shanks and standing wide on their pins, lengthy bodies and well-sprung ribs, and the whole frame indicating a grand carcass for both mutton and wool. Many of these features are distinguishable from our engraving, though the sheep themselves should be seen to be judged of properly. This flock, indeed, is so highly appreciated that not only the rams are in high request, but the draught ewes of the flock are eagerly purchased by breeders wishing to improve their own stock.

Any of our readers taking an interest in such matters, that may happen to be in Scotland about the time of the Kelso sale, say about Sept. 10th or 15th of each year, would do well to make a point to be present at it and judge for themselves of the Border Leicesters; and if in the neighbourhood at any other time, we are assured by the liberal proprietor, will be welcome to see the Mellendean flock, the shepherd taking much pride in showing them to strangers. He talks to his pets like children, and has a separate yarn to tell about each, even his dog hob-nobbing with them on friendly terms. The locality, too, has many attractions in natural beauty, and is associated with much that is chivalric in song and story.

Fattening Cattle.

The unusually short supply, and consequently high price, of beef during the past year, owing mainly to the demands of distant markets, and comparatively cheap means of transportation to them now offered through the competition among lines of railway concentrating towards the great centres of commerce and manufacture, render the feeding of cattle for the purposes of the butcher a much more profitable operation to the farmer than it has hitherto been. He no longer needs to depend on his neighbours, or a small local

demand, for the disposal of what his farm can furnish in the way of flesh meat, but will find men who make it their business to act as factors between the producer and consumer at all times, going through the country, or attending local fairs, ready to buy up at fair prices every head of live stock they can find in a condition suitable for the butcher.

The age at which cattle can be profitably fattened will depend much upon their breeding, and the manner in which they have been reared. Steers or heifers, having from half to three-fourths Shorthorn or Hereford blood in them, and that have been kept in a thrifty growing condition from calfhood, are usually sufficiently advanced to be put up to fatten when from thirty to thirty-six months old. Pure-bred animals of Shorthorn or Hereford blood may be profitably fattened at an earlier age. A cross of one-half to three-quarter Devon blood on common stock makes an animal that can go into the stalls at two years old, if it has been kept in good growing condition. Common native cattle can rarely be profitably fed for the butcher till they are four years old. If cattle are put up to fatten before their growth has sufficiently advanced, so as to bring them near their full capacity of laying up substance, much of the food given them, instead of going to make them fat, will be wasted in adding bone and muscle, which could have been obtained more cheaply by giving them time to complete their development on ordinary keep. Besides, the effort to fatten an animal when in an immature state can only result in producing meat of a very inferior quality, and commanding a much less price than if the same animal had been kept on longer until its frame had become solid and well knit together, its muscles developed to their full capacity, and its stomach capable of digesting and assimilating a larger amount of food than is actually required to sustain the ordinary growth and wear and tear of life, without derangement of its vitality.

There are every year great numbers of young cattle sold to the butcher, or slaughtered by farmers, and their carcases brought to market at the close of the grass season, when they are in a state of development that renders their flesh of an intermediate quality between veal and beef, without the tenderness of the one or the rich juiciness of the other, but as flavourless and worthless as any flesh can well be. It is sheer folly to sacrifice such animals for the sake of the paltry saving of a few months' food, when by keeping them over one winter more they would bring nearly double their present value, and be fit to make into beef that is full of rich savoury juices.

Stall feeding cattle, judiciously conducted, presents to the grain grower the most efficient, cheap, and desirable method of keeping up the fertility of his farm, and the most profitable means of disposing of his surplus hay, roots, and coarse grains. The manure made from such cattle, were it all the profit derived from the process, would be amply sufficient to repay the farmer for his trouble; while the hay and grain so consumed would sell in the shape of beef for a higher price than if it had been taken to market; for it must be borne in mind that in turning roots, hay, and grain into meat, we get the price that they would bring in a higher and more distant market, without the risk and expense of transportation to it, while the same articles, hay and roots especially, would be governed as to price by the local demand of the immediate neighbourhood where they were grown, which is often very low. The greatest demand, and consequently highest prices for beef, now extend over a much longer period of the year than formerly, the facilities for transportation by rail rendering it possible at all times to furnish a constant supply of fresh meat to distant markets, when formerly much of the summer consumption was restricted to meat slaughtered in late autumn, and salted down for future use. This has in a measure rendered the winter fattening of cattle, in order to supply a spring and summer demand, much more certain to yield a profit than formerly, and greatly increased the demand for meat, now that it can be so readily supplied at all seasons in a fresh state. In a future article we may discuss the matter further, and give the best methods of profitably feeding cattle for the butcher.

Selecting Stock Rams.

In order to breed sheep successfully and profitably, much depends on the judgment used in selecting the rams to be used in the flock. It should be the aim of every farmer to endeavour to raise the standard of the stock on his farm, in an even and gradual manner, by using male animals of as much higher a degree of excellence each year as his means will afford. He must also keep in view a certain object in breeding. If he is so situated that he can profitably raise sheep solely for the purpose of turning into mutton, he will find his profit in using Leicester or Southdown rams of pure blood to put to common ewes. If wool is his object, he will find the use of Cotswold rams best attain the end in view, as that class of wool not only commands the highest price, but is also more certain to be of uniform quality, and to yield a high average of weight of fleece throughout a flock.

We will suppose a farmer has a flock of ordinary common grade sheep, and desires to improve them. He can begin the first year by using a ram lamb or two, costing from $10 to $15 each. This will carry him through two seasons, by which time the ewe lambs of the first season will be gimmers, ready to take the ram. He should then get one of higher quality, say a shearling or two, costing $20 to $30 each. Two seasons after this he needs one of still higher quality, and of as good size as can be had, costing, we will say, $50. After this he should change his rams every year, giving a good price to get a first-class animal from some well-known and reliable ram breeder. In all cases it is particularly advisable not to use as stock-getters in his own flock any of the male animals bred in it. All the ram lambs in the flock not intended to be sold off as lambs to the butcher should be castrated, and raised as wethers until such time as the flock has reached the highest degree of excellence it is capable of attaining, when the ram lambs, if then good, may be kept for sale as breeding rams, and will probably bring good prices.

It is a poor policy to continue breeding and feeding sheep that will realize but from $3 to $5 each from the butcher, when by a little extra outlay in the way of procuring male animals as stock-getters that will raise the standard of the flock, he can obtain from $6 to $10 each for what he has to sell, and in a year or two more, by perseverance, the flock can be raised to such a high standard as to readily command from $12 to $18 or $20 each for what can be fed up for the Christmas or spring markets, or sold as breeding stock. It costs no more to feed such animals so as to keep them in good growing store condition than it does those of inferior quality. The great aim should be to obtain animals that combine good size and form with early maturity and aptitude to fatten, and in the case of wool growing, the animals that can carry the largest fleeces of the true quality of the breed are the most profitable to keep.

Stallions for Common Labour.

There are very few geldings in France. The reason is, the stallions are not unmanageable, vicious, and dangerous as work horses, but docile, obedient, easily managed, and intelligent. There is nothing in the nature of things to prevent our having the advantage of the greater toughness, strength, spirit, fearlessness, safety, (in being less liable to take fright), freedom from disease, and longer serviceableness of the stallion over the gelding, were it not that we and our ancestors have so abused the temper of the horse, that his progeny exhibit, among the unaltered males, vicious and treacherous tempers, such as make them unsafe and unreliable as work horses, even under the kindest and most uniform treatment.

The English thorough-breds, unexcelled for spirit, endurance, fleetness, and wind, are the most vicious of all horses. They came from the gentle, docile, affectionate Arab, and it is only the training and abuse of the English stableboys and grooms, we verily believe, which have thus, in the course of generations, ruined the temper of the most noble of the breeds of horses. Its blood is infused through all our common stock, and to it we owe most of the characteristics for which we value our horses. Where thorough-breds have been bred for generations under

different treatment, as under the handling of the negro grooms and riders of the Southern States, their tempers improve, and extraordinary exhibitions of vice are rare, even among stallions. The habit of using stallions is followed a good deal by French Canadians, who send to this country so many of the so-called "Canuck" horses. These horses are small, close-knit, and powerful, and when entire, tough beyond comparison. Wherever we meet with them, they are praised for easy keeping qualities, great endurance, and freedom from ordinary ills, and are seldom complained of as vicious. Do we not, in our ordinary treatment, sacrifice a great part of the usefulness and serviceableness of the horse, in rendering him more tractable, more liable to disease, and less intelligent and spirited? Is it not worth while to make the experiment oftener of rearing stallions for labour, though it require more patience, gentleness, and kindness, on the part of those who handle them, and repeated floggings, administered with a will, to any stable boys who dare to pinch or tickle, or to ruffle their tempers? —*American Agriculturist.*

Kelso Ram Sales.

The Kelso *Chronicle* says that the sheep show and ram sales at Kelso took place on the 9th of September, and secured, as usual, a large attendance of spectators and buyers. Some of the prize animals were purchased for Canada. The Mertoun lot of Lord Polworth once more obtained the first place, the highest price realized being £100—a very high figure, but less by £9 than the top price for the Mellendean lot last year. The highest average this year was £22 14s., against £16 9s. last year. Miss Stark's Mellendeans were late in being put up, a circumstance which, no doubt, reduced the competition and the prices, but notwithstanding, they excited a keen rivalry amongst the bidders, and obtained the second highest average. The total number of entries was 1737.

What it Takes to Soil a Cow.—Desiring to know just how much saving there is in soiling, and having an excellent piece of clover, in its best estate, just coming into blossom, we measured forty square rods and commenced feeding it to seven cows and four horses; it fed them liberally, fifteen days. The two succeeding years we tried the same experiment, the animals differing somewhat, but with the same result—in each case we found forty square rods equal to the summer feeding of a cow. But these crops of clover were very heavy, and could not always be equalled; yet allowing for contingencies, we came to estimate one-half acre of land in good condition, in clover, as adequate to summering a cow; thus making soiling equal to from four to six times the space in pasture. We tried afterwards much larger experiments—soiling thirty-five cattle and horses, and using some land in much poorer culture, but we found the saving, comparatively, quite as encouraging. We selected one hundred acres—barely sufficient to have pastured this number of animals—ten of it in clover, oats, and sowed corn; we fed them from the 20th day of May to the 1st day of December. We had a surplus of sixty-five tons of hay, after feeding these animals six months and ten days, which sold in the barn for $972. It required six hours' labour per day to soil them, which amounted in those cheap times to $65. One hundred loads of manure were saved in fine condition, worth, at least, $50 more than the droppings of these animals in pasture. The expense of cutting and housing the sixty-five tons of hay was $1 50 per ton, or $97 50, which added to the labour of soiling makes $162 50, leaving $359 50 as the net gain of this soiling experiment.—*Live Stock Journal.*

Stock and Crops for Farms.—"A Northern Farmer," in the *Mark Lane Express*, gives his opinion on this subject as follows: "In this paper much stress has been laid on the necessity of keeping a heavy stock constantly on the farm, yet some care must be exercised to provide a proportionate amount of food, and to have it for every season, otherwise, instead of profit, the year's transactions will end in loss. The farmer who is overstocked, is always in trouble; in spring he must stock the pastures too early for the want of house food, and in autumn he must permit the cattle to remain in the fields until, through exposure to bad weather and insufficiency of food, they become greatly reduced in condition. If to avoid this he begins early on his stock of roots and hay, he is run out, very probably, in March, the very season when the lengthening day and the chilly cutting winds cause increased consumption, and a struggle of some kind must be made to hold them over on purchased food until something can be picked up on the pastures. The full supply of food tells on every animal, but of course more noticeably on those whose produce is being daily turned into cash. The widely-distended bag of a well-fed cow as she comes from the pastures to be milked, and the sense of relief which she unmistakably shows when the process is completed, is both a source of gratification and of profit, and is in wide contrast to the limp, half-empty appearance of the udder when the cows are in bare pastures, and have to roam about continually in quest of food. No amount of care or good management on the part of mistress or maid can make up for this oversight on the part of the master, and when, on making up the year's receipts, he finds the amount to be little over half what it reasonably might have been, he can only blame himself for his shortsightedness in keeping more cattle than the food he had provided was able to sustain. Breeding ewes tell also very forcibly by the return which they give, whether they have been liberally fed or not—any deficiency in food telling at once on the milk, and the lamb in consequence ceases to grow, and becomes stunted and profitless.

Veterinary Department.

Nephritis, or Inflammation of the Kidneys in Horses.

Although the kidneys act very powerfully in horses, fortunately they are not so liable to acute inflammation as some other organs. The causes of this ailment are varied. Among them may be mentioned prolonged and severe work, or the abuse of diuretic medicines, as in giving large doses of rosin and saltpetre, which is often done with the intention of improving the condition. Continued irritation has an injurious effect, weakening those highly sensitive organs, and rendering them liable to disease. Another common cause is the eating of hay that has been improperly made, and certain grasses that possess diuretic properties. It may also be produced from injury, as in connection with a sprain of the psoas muscles, or in saddle horses from carrying heavy and continued weight. It also occurs in connection with some diseases of the respiratory organs, which have a tendency to arrest generally the various secretions of the body, and it is occasionally induced by the application of cantharidine blisters over a large surface of the body. The active principle becomes absorbed and over-stimulates the kidneys.

The symptoms of nephritis are more or less fever, according to the severity of the attack. The pulse is quickened, the coat is staring, and the surface of the body changes suddenly from hot to cold, the belly is somewhat tucked up, and pressure over the loins causes the horse to cringe downwards; he walks with a stiffness of the hind-quarters, and will also lie down and roll, but not so violently as in a case of inflammation of the bowels. Now and again he will place himself in a position as if desirous to urinate, and strain violently, and when urine is passed, it is invariably very high-coloured, and frequently tinged with blood. This is more particularly the case when the inflammatory action is produced by the presence of some calcareous matter in the kidneys. In severe cases the horse turns his head to the flanks, indicating clearly the seat of his suffering.

In the treatment of this disease, the excretions of the bowels and skin should be excited so as to relieve the kidneys. A good plan is to apply over the body a large blanket wrung out of hot water. A moderate dose of purgative medicine should be given, say a pint of linseed oil combined with one drachm of calomel. Injections of tepid water are also beneficial by exciting the action of the bowels, and also in acting as fomentations to the inflamed parts. When the pain is very severe, a dose of two scruples of opium with one scruple of calomel has a tendency to relieve the pain. A mustard plaster over the loins is also bene-

ficial. Nitre and rosin should not be given in this complaint, as these medicines increase the irritation. The horse should be encouraged to take mucilaginous drinks, as linseed tea, hay tea, &c., and be fed sparingly on mashes of bran or on certain kinds of green food, as grass and lucerne, when it can be conveniently procured.

Strangles.

This is a disease peculiar to the young of the equine species. It usually attacks the colt about the period of dentition. There is an appearance of general bad health; the colt appears to be out of sorts; he is not so playful as was his wont, gulps his water and fails in his feed. His coat stares, and in a word, he has a dumpish appearance. Very soon a swelling shows itself under the jaw, and at the same time a creamy discharge takes place from the nostrils. This swelling can be distinguished from that which occurs in glanders, by its uniformity. In glanders the swelling is of a nodular character, and generally at one side, with a tendency to adhere to the jaw or to some of the surrounding membranes. The discharge is usually only from one nostril, and in the nostrils there are deep angry ulcers, with rugged overhanging edges.

There is another form of strangles called *bastard strangles*. In this form there is no discharge of nasal gleet; the swelling may appear on any of the groups of lymphatic glands; it may even settle on some of the internal organs, lungs, mesentery or brain. Every endeavour should be used to make it break externally. Sometimes, in genuine strangles, if there has not been a free discharge externally, it goes in and settles on the brain.

I had an opportunity of examining the brain of a horse which had died from this cause, and found that there were two or three large abscesses on the *cerebrum*, and two on the *cerebellum*. The animal had got what the owner called "over the distemper," although not thriving as well as he ought. At length he became delirious, and finally died in a state of coma.

The treatment for strangles is very simple. Medicine, in most cases, does more harm than good. Keep the colt in a comfortable loose box, give the most nourishing food possible—boiled barley for example; steam the nostrils well. This may be done best by cutting the bottom out of an old sack and then drawing it over a horse-bucket; then put a boiling hot bran mash in the bucket, and place the colt's head in the bag. A large bran or linseed poultice should be put under the jaw, or wherever the swelling appears. The poultice cloth should be a sheet, to cover the entire head, with holes cut for the nose and ears, and tied at the back of the ears.

Sometimes the colt is in danger of immediate death from dyspnœa; then tracheotomy should be performed; this cannot be done without the assistance of the veterinary surgeon.

This disease is contagious, empirics to the contrary notwithstanding.

In ordinary cases, with the above treatment, the colt will be as well as ever in three weeks.

A. M. C.

The Dairy.

Why Winter Butter is Poor.

The month of June, all things considered, is regarded as the best month in the year for manufacturing butter. This is due to a combination of circumstances. Drought seldom commences so early in the season; accordingly both feed and water are abundant. The grasses which are the natural food of cattle are then in a state to furnish not only the most food, but that of the best quality for prodneing rich milk. The insects which are so troublesome later in the season have not made their appearance in large numbers. The air is not tainted with bad odours as it is later in the season. The temperature is very favourable to the rising of cream, neither so warm as to cause the milk to sour quickly, nor so cold as to prevent the separation of the oil globules.

Another season very favourable to the production of good butter is the early fall. At this season we ordinarily have rains that bring up the grasses to something like the plenteousness they gave us in the spring. Many of the insects so plenty in midsummer have disappeared, and the temperature throughout the day is more uniform.

When winter arrives, however, the quantity of the butter is greatly lessened, and its quality is much inferior. In truth, the chemical composition of the butter is considerably changed. The ingredients are different, not in kind but in quality. Oleine, which is the softer fat in butter, is much more plentiful in summer butter than in that made in winter. The colour of winter butter is also different from that made in summer. The former is almost white, while the latter is golden.

The unfavourable condition and appearance of winter butter are partly owing to causes that we cannot control, and partly to causes that we can, in a measure, obviate. Dry food will produce less oleine than fresh green food. We, however, can prevent a very great diminution of this fat, by cutting our grasses earlier, and curing them so that they will retain all their natural juices and their aromatic qualities. We can prevent the lessening of the quantity of milk to the extent that usually happens by keeping our cows as well supplied with food and drink as they are in summer, when they can feed at will, and can procure water whenever they wish. Giving cows food and drink only after long intervals of fasting has a most injurious effect on the secretion of milk.

The light colour of butter in winter is, doubtless, due to two causes. The oleine is of a darker colour than the other ingredients of the butter, and the more scanty it is, the paler will be the colour. The chief cause, however, of winter butter being so light coloured, is due to the cream becoming bleached before the butter is churned. Cream has its richest colour when it first rises to the surface, and if it is churned in that condition the butter will be yellow. If it remains, however, exposed to the light, particularly if the temperature change, the rich yellow colour disappears, and it will be found to be impossible to produce golden butter from white cream.

Let any one try the experiment of taking some yellow cream with a little milk below, and let this remain for two days or more in a glass vessel, and mark the changes that take place in the colour. At first the line between the cream and milk is very distinctly marked, but after a little, the cream has become bleached to such an extent that it cannot be distinguished from the milk in colour. Winter butter is white, then, because the cream is ordinarily kept too long before it is churned. It is very hard to obviate this difficulty in small dairies, particularly when the cows are so poorly provided for that their milk becomes very scanty. It is, doubtless, better, even if the supply of cream be small, to churn as often as we do in summer, using a churn proportionally smaller.

Winter butter has a poorer flavour than grass butter, from a variety of causes. The food the cows eat is devoid of the agreeable taste common to the grasses while growing or in blossom. Besides this, the milk is too often kept in a room the atmosphere of which is foul from the odours arising from cooking. The milk, at such times, acts the part of a disinfectant, and carries the stench of th kitchen into the cream pot, and from thence into the butter jar.

Good butter can be, and often is, made in winter, but it is only done by having all the circumstances surrounding the cows—the milk room and churning—as nearly as possible like those in summer. The cows must be fed on food rich in sugar, and never be stinted in amount. The milk must be set in a room the air of which is pure, and the temperature of which does not greatly vary. And lastly, the cream should be churned when it is not above 24 hours old. —*Prairie Farmer.*

Grinding Cheese Curds.

The process of grinding curds seems to be coming gradually into vogue. One day last week we visited Dr. L. Wight's factory, at Whitesboro, to witness the operation of grinding by the use of a small oscillating engine, which does pumping, churning, etc. The curds are first treated after the American Cheddar method, by running off the whey just as it begins to acidify, and allowing the curd to drain and air while the acid is developing. It is then taken out in large chunks, put into the sink, run under the curd mill and ground, or rather picked to pieces, salted, and immediately put to press. If allowed to get too cold, it is difficult to make the cheese face. The curd mill or picker tears the curd to pieces as fast as one can conviently feed it.

By this process, a good deal of stirring is saved, no strainers or racks are needed, and the salting is done with more certainty and evenness. There is not so much danger of getting the curd too sour, and a few moments' delay is not of so much consequence as it is when the curd lies in the whey. It seems to be certain that a firmer cheese is secured. The gas which makes open cheese either escapes or does not generate, and hence a tainted or floating curd makes a cheese that stands perfectly true on the arnges without the least sign of "huffing."

That there is any real improvement in the quality of the cheese we are not prepared to say. The indications of tainted milk are still perceptiblo in the flavour, and cooling the curd retards putrefactive action, which will sooner or later show itself, especially if the cheese be subjected to excessive heat in the rail-car, on shipboard, or in the storehouse. Still, the advantages of the Cheddar process, and of grinding a tainted curd, are apparent; but we concur in the opinion of Dr. Wight that, if the milk is all right, the old method is as good as any, so far as the quality of the cheese is concerned.—*Utica Herald.*

Sulphur as a Deodorizer.—The *Maine Farmer* says:—"One night a sort of domestic animal, known as a skunk, took up his abode in the back entry of a house, and being disturbed by the cat, emitted a most disagreeable odour—as he is always sure to do when he is at a all suspicious that his rights are being invaded. The dairy being in the neighbourhood of where the conflict took place, it became infected with the noxious odour, when our friend, in his haste to cleanse the premises, burnt some sulphur in the room. The effect was magical, as it completely neutralized all the foul smell."

Corn Leaf Fodder.—It has long been the habit in the South, where hay is scarce and poorer than here, to rely largely on cured corn leaves for wintering all kinds of stock. These leaves are stripped from the corn, the talks being left in the field till winter. The *Arkansas Farmer* tells how it should be done: "As soon as the shuck ripens, begin to strip the blades. Do not put the fodder on the ground, leaving it until evening to bind. The method of tying in small bundles as it is stripped, and hanging on the stalks to dry, is best. When about three-fourths cured, gather and throw in good-sized close heaps, late in the evening, and let it go through a heating process during the night; next day throw open the heaps—the heat will dissipate the remaining moisture, cure the fodder sooner, and give it, at the same time, a tenderness and flavour much relished by the stock. Spare no pains to cure it well—if mouldy and dusty, it may prove more than worthless."

Horticulture.

EDITOR—D. W. BEADLE,

CORRESPONDING MEMBER OF THE ROYAL HORTICULTURAL SOCIETY, ENGLAND.

The Fruit Growers' Association of Ontario.

This Association held its regular autumn meeting in St. Catharines on Thursday the 22nd Sept., 1870. There was a very full attendance of members, and a very fine display of fruit. The collection of grapes was very extensive, embracing a great number of varieties, and many of the newer sorts, including the Rumelan, which latter sort was exhibited by Mr. John Brown, of Thorold, and Messrs. Coleman and Merritt, of Geneva, N. Y.

The meeting was called to order by the President. The minutes of last meeting were read and the following Committees appointed:—

Committee on apples and pears—Messrs. Dougall, Morse, and Bennett.

Committee on grapes—Messrs. Read, Taylor, and A. M. Smith.

Committee on other fruits—Messrs. Mills, R. M. Ball, and Saunders.

Committee on wines—Messrs. Farrell, Logie, and White.

Committee on seedling fruit—Messrs. Cross, Arnold, and Halton.

The discussion of the best method of pruning and training the grape vine was then entered upon.

Mr. Y. Keating, of Jordan, stated that he trained his vines on the arbour system. His vines did not cover the top of the arbour trellis as yet, and therefore he allowed the vines to fruit on the perpendicular part of the trellis; but as soon as the vines are able to cover the top he intended to prune off the branches from the perpendicular part of the trellis and confine the fruit and foliage to the top or horizontal part. He has about an acre and a half planted with the Delaware, of which one acre is trellised. He pruned in March and April, and has three canes to each vine, but has not practised trimmer pruning, but is of the opinion that a little pinching in during the summer would be serviceable. The vine now exhibited by Mr. Keating and covered with ripe fruit has been planted six years. He manured his vineyard two years ago by ploughing under clover, and last spring applied a dressing of well-rotted barnyard manure. His soil is sandy loam, the soil about eight inches deep, with a hard, yellow sandy subsoil, having a hard pan two and a half feet below the surface, and clay from eight to nine feet down.

John W. Ball, of Niagara, trains his vines on the arbor trellis plan, no foliage allowed on the sides of the trellis, the vines are trained up the sides of the posts to the top of the trellis, and the sides are open all around, so that he can drive under the trellis in every direction and cultivate with the horse every part of the vineyard. The posts are seven feet long, not planted in the ground, but set upon a flat stone placed under the foot of each post. The horizontal bars are nailed on to the top of the post, so that the whole weight of the top rests on the ends of posts; and braces run from the posts to the horizontal bars. Made in this way, there is no rotting off of posts, nor strain upon a nail, nor blowing down by the wind, nor heaving out of place by the frost. His soil is a clay loam about a foot deep, with a retentive clay sub soil, well under-drained. Has manured them with leached ashes. His vines are planted twelve feet apart each way. Of course, his vines get no winter protection.

W. H. Read, of Port Dalhousie, said that he pruned both in the fall and spring, mostly in the fall because it was more convenient to do it then. He varies his pruning according to the habit of the vine: those of very strong growth and vigourous habit requiring to be left with longer shoots than those of a slower habit of growth. He has never seen any evil to result from fall pruning. Some of his vines are trained to stakes, others to upright trellises; has not tried the arbour trellis; thinks the best ripened grapes are those near the ground, because they get the radiated heat of the earth. His soil is a sandy loam, about eighteen inches deep, with a hard-pan subsoil, located on the south shore of Lake Ontario. He thoroughly manured the ground with barn-yard manure when he planted the vines ten years ago, but has not given them any manure since. High manuring may produce larger grapes, but poorer in quality.

Jas. Taylor, of St. Catharines, prunes his vines in the fall and finds that they do not get injured by the winter in consequence. He has more leisure to prune in the fall, and therefore prefers to do it then; is also satisfied that grape vines are not benefitted by high manuring, and has abandoned the practice of manuring them except by a mulch of barn-yard litter over the roots. His soil is a limestone gravel, naturally porous and well drained. Some of his vines are on a side hill, with a western exposure. He has also given up the practice of summer pruning, having become convinced that much summer pruning is injurious, and now contents himself with merely pinching in the ends of shoots that seem to require it.

The meeting adjourned until 2:30 P. M.

AFTERNOON SESSION

The President called the meeting to order, and called upon Mr. Haskins, of Hamilton, who remarked that he preferred the arbor system of training and Spring pruning, especially for the free-growing sorts, such as the Clinton and its confreres. He uses as fertilizers leached ashes and bone dust and stable manure. He mixes two tons of bone dust with four tons of ashes and four tons of gypsum or plaster, and applies it to five acres of vines. He finds that many varieties kill back badly in the winter if fall pruned, and therefore he prefers the spring. He has nine-and-a-half acres of grape vines in cultivation, planted two years ago last spring. The vines are showing a little fruit this year. The sorts are mostly Rogers' hybrids, with a good many Delaware and Clinton, with about twenty other sorts for experiment. Is much pleased with the Iona, Delaware, and Rogers No 4. Thinks the Creveling one of the very best of wine grapes, but the bunches are very imperfect, because the berries do not set well, but are too scattering. The soil is sandy loam, with clay bottom, well underdrained.

Mr. Babcock, of Lockport, New York, said that vine cultivators in the United States were now beginning to prune larger and train higher. They have heretofore been in the habit of cutting off too much of the vine at the winter pruning. If the vine sets too much fruit they thin it out, either by cutting out the branches or by cutting off the entire branch, fruit and all. They usually cultivate on upright trellis, composed of three wires, fastening the vines to the wires with willow twigs or rye-straw. There is a new wire contrivance for fastening the wire to the trellis known as Underhill's patent wire back. They have a machine for tightening the wires of the trellis.

Here several members described different contrivances for tightening and slackening the wires of the trellis; the most simple of all seemed to be one described by Mr. Barnes, of Hamilton, but we forbear attempting to give a descrip tion, hoping to obtain from Mr. Barnes a full description with illustrative drawings.

The meeting now proceeded to the consideration of the best methods of grafting the vine.

W. H. Mills, of Hamilton, said he had not been successful in grafting a vine that was already established growing in the soil, but when he dug the vine up and then grafted it and planted it out again, he had met with very good success.

W. H. Read, of Port Dalhousie, said that he had grafted in the fall and then carefully protected the grafts from the frost. In this way forty-five per cent. had done well.

C. Arnold, of Paris, had succeeded well in the same way; it was not necessary to have the bark of the scion and stock fit together, as in grafting the apple, but they grew just as well when inserted in the middle of the stock.

Mr. Brooking, of Ancaster, planted out some old vines, thirteen in number, and then grafted them. Of these twelve grew. This was done in April, and the crown where the graft was inserted was covered with earth, leaving one head of the scion at the surface of the ground

Mr. Dougall, of Windsor, had tried grafting the vine, but always failed.

Hugh Smith, of Sarnia, exhibited to the meeting some samples of a method which was a combination of layering and grafting. The branch of a tree or shrub is bent down so as to admit of the twigs being readily layered; the twigs are then tongued on the underside as for layering. A piece of root of the same

species is cut about six inches long, pointed like a wedge at the upper end and inserted in the slit made in the twig, the bark of each being fitted exactly on at least one side, and fastened to its place by tying with basswood bark or cotton yarn, and then the root is inserted in the ground, with enough of twig to keep the point of union moist below the surface of the ground.

The accompanying sketch may illustrate the process. a is a branch bent down to the ground. b is a hooked peg to hold the branch in place. c c are the twigs slit on the under side. d d are pieces of root inserted into the twigs at the slit made on the under side. e shows the wedge form of the root at the end to be inserted in the slit.

Mr. Smith stated that he did not suppose that this method would be generally used, but that it would be found to be of service in the propagation of those trees, plants and shrubs that are difficult of propagation by the ordinary methods.

President Burnet, of Hamilton, had cut his grape scions in the fall and kept them in a cool place, where they remained in a dormant state until the vines were in full leaf in June; than he inserted a scion of two or three buds long in a branch of a growing vine, in the usual manner of cleft grafting, fastened the graft by tying, and then buried the place of union in the soil sufficiently deep to keep it moist; and, in order the more certainly to secure this, he covered the place of union, before burying, with a thick coating of cow-dung. In this manner he had been very successful.

The best method of manuring the vine was here taken up.

Mr. Arnold, of Paris, would use very little manure, and never use coarse or highly nitrogenous manures.

Mr. Mills, of Hamilton, would manure according to the requirements of the variety. Some varieties, of the Delaware, required high culture and would never yield their best results in poor soil; others, as the Diana, required no manuring, but yielded their finest crops and ripened them best in a poor soil abounding in lime.

Dr. Cross, of St. Catharines, manures only those varieties which are slow growers.

Mr. Farrell, of Cayuga, would manure according to the habit of growth of the variety.

Mr. Bennett, of Brantford, thought that vines succeeded best in the natural soil; at least he would not manure highly.

Mr. Read, of Port Dalhousie, uses leaf mould, cow dung and ashes.

Mr. Taylor, of St. Catharines, top dresses with coarse stable manure, more as a mulch than otherwise.

Rev. Mr. Campbell, of Niagara, has an old Isabella vine growing in grass in the lawn, which fruits abundantly, and ripens its fruit well.

Mr. Mills also had an Isabella that had stood for seven years in sod that bore fine fruit and ripened its fruit.

Dr. Cross, of St. Catharines, cultivates the ground between his vines, and never failed to ripen the Isabella except in 1869; and when there are no severe September frosts his Catawbas ripen. He prunes on the renewal system, and finds the Isabella and Catawba grow finer fruit and ripen it better on young canes.

On the subject of winter protection of grape vines,

Mr. Saunders, of London, said that he was of the opinion that a grape vine which required winter protection was not worth having. He had found most of our varieties sufficiently hardy without any winter protection, though his Diana had been killed to the ground.

Mr. Read, of Port Dalhousie, protects by a light covering of pure soil or earth. Other coverings are apt to afford a shelter for mice.

Mr. Arnold, of Paris, finds few varieties that succeed without winter protection. He thinks branches of evergreens the best winter protection that can be used. Inquiry was made as to the hardihood of his seedlings, to which he replied that he had supposed that they were all hardy, but that of late the white variety seemed to be tender. Brant, Canada, and Cornucopia were tolerably hardy.

Mr. Paffard, of Niagara, protected only those of foreign origin, as the Sweet Water, Zinfandal, &c.

Mr Farrell, of Cayuga, used formerly to protect all his grape vines in the winter, but had gradually abandoned the practice, and now only protected newly planted vines during the first winter.

Mr. Bennett, of Brantford, had been in the habit of protecting his vines every winter and has uniformly had good crops, but last winter he left his vines exposed, and they were badly winter killed. He thought it quite possible that having been heretofore protected they were now less able to withstand the winter than if they had never been protected, and hence the injury last winter to even old canes some inches thick.

Mr. Arnold, of Paris, suggested that vines can be too much covered, especially with soil, for if buried too deep the wood of the vine is kept too moist and the buds rot.

On the subject of Insects on the vine,

Mr. Bennett, of Brantford, remarked that he had been remarkably exempt, the only insect he had seen was one that had punctured the berries of the Diana.

Mr. Mills, of Hamilton, had been very much troubled with the vine thrips, but could not suggest any mode of getting rid of them.

Mr. Dougall, of Windsor, had noticed that the thrips injured only the thin leaved sorts such as the Delaware and Clinton, but was unable to injure the thick leaved varieties, such as the Concord, &c. He had been very much afflicted with a worm in the berry of the grape, probably the same as the insect in the Diana mentioned by Mr. Bennett.

Mr. Saunders, of London, mentioned that the thrips could be very much lessened by having a man pass through the vineyard bearing a lighted torch, while another went with him and shook the vines; the thrips, disturbed from their hiding places under the leaves, flew into the blaze and perished. The flea-beetle could be easily killed in the larva state, and it only required proper attention to keep this pest in subjection.

Members mentioned the varieties of grapes which they had found, on the whole, to be the earliest. The four sorts which were mentioned by nearly all the members were the following, viz: Hartford Prolific, Adirondack, Massasoit (Rogers No. 3), and Creveling.

Mr. W. H. Read, of Port Dalhousie, stated that he had some seedling grapes which ripened in August, and which he fully expected would prove to be perfectly hardy, and ripen earlier than any of those that had been named.

The meeting then took up the subject of Pear trees, their cultivation, manuring and pruning.

Judge Logie, of Hamilton, did not give his pear trees any special cultivation; he supplied them liberally with ashes and an occasional top dressing of manure; had experienced a little blight, and some spotting and cracking of fruit.

Mr. Jas. Taylor, of St. Catharines, had not found the cultivation of pear trees very satisfactory; has lost a good many trees—believes very little. His soil is a gravelly loam; trees are dwarfs, some have thrown out roots above the quince stock and become standards.

Jas Dougall, of Windsor, has a heavy loam and a strong clay loam; had tried 350 different sorts on the quince stock. Some of these grew finely, many would not grow at all. Had learned that some sorts were not suited to the quince stock and should never be grown as dwarfs, such as the Bartlett, Seckel, Doyenne d'Ete, &c.; on the other hand the Beurre d'Anjou, Duchess d'Angouleme, Ananas d'Ete, &c., would thrive well as dwarfs. He would plant a pear orchard of Standards and dwarfs together, setting the Standards thirty feet apart each way, and put dwarf trees between them so that the trees would stand fifteen feet apart each way. Has no blight. Angiers quinces are the only suitable stock for dwarf pear trees. In cold latitudes strong shoots should be pruned back to the ripe wood, early enough to heal over before winter.

A. Straight, of Watford, had found the pear tree to be generally healthy and prosper best in clay soil; they should not be too highly manured, especially with raw manures. He named the Flemish Beauty as one of the most hardy and desirable varieties.

Thos. Ketzs, of Grantham, preferred the Standard pear trees, especially of the Bartlett and Flemish Beauty varieties. Dwarf pear trees need good culture.

Mr. Arnold, of Paris, said that all young trees should receive good culture.

Mr. Saunders, of London, had just visited two distinguished cultivators in the United States who advocated and practiced opposite systems of pear culture. One adopts the system of no pruning — the other prunes considerably. He thought that if results were a just exhibit of the effect of the two methods, the man who pruned his trees had the advantage decidedly. This was Mr. Quinn, whose pear orchard is near Newark, New Jersey. He plants only dwarf trees, at one year old, setting the point where the bud was inserted six inches below the surface, trains the branches low, and plants only a few sorts. He gets from $12 to $16 per barrel in New York for the Duchess d'Angouleme; from $12 to $14 per barrel for the Seckel: $20 per barrel for Rhenish Beauty; for the Bartlett $10 per barrel, and for the Beurre Clarigeau $25 per barrel. He does his pruning in the spring, about the 15th of March, and cuts the strong growers well back.

Mr. Morse, of Smithville, thinks that while the pear should have liberal culture, yet the trees can be injured by too liberal application of barn-yard manure. He uses leached and unleached ashes with good results, and has never yet failed of having a good crop of pears.

The session having continued until nearly ten o'clock, p.m., at which time many of the members were obliged to leave for the train, the Association adjourned, to meet in Toronto at the annual meeting, to be held on Tuesday evening, the 4th of October.

Some samples of fruit that were sent by express, and intended for exhibition at the meeting, failed to arrive in time; among these a branch of an apple tree which bears small Russet apples, and large smooth apples resembling the Vaudievers. This was sent by D. Hammond, Sheridan, P. O., who writes thus:—"I also send for your investigation a limb bearing two kinds of fruit. I have shown it to different persons, and told others of it, but none can account for it in any way. You will see what variety the fruit is of, the large apple being the kind it bears, the russet being the mystery. If the Association can explain in any way the cause of its bearing the russet without human agency, which it certainly does, you will confer a favour. I send this last as a fact of interest that has fallen to my experience, as requested in the circular."

The several committees appointed to report on the different fruits exhibited handed in their reports, but there was not time to read them to the meeting.

Many reports have been received by the Secretary of the growth of the Rumelan Vine. Nearly all state that it has made a good growth and ripened its wood well; two or three state that the leaves were attacked with mildew, in which cases, of course, the wood has not been well ripened.

Members who have not sent in their report on the growth of the Rumelan Vine, received by them from the Association, are requested to do so without delay.

The subject for discussion at the meeting on the 4th Oct. will be the benefits of fruit culture as connected with the farming interests of the Province.

Vine Culture in Australia.

To the Editor.

Sir,—In a recent issue, I read some remarks on Vine Culture, and thinking I might interest, if not benefit, those who have planted the grape in Canada, I purpose giving a description of the propagation and culture of the vine as practised in South Australia, in which Province I resided upwards of twenty-five years, and am perfectly acquainted with every mode of treating the vine in that colony—whose vineyards have spread over many thousand acres, the produce of which is largely and favourably known in the Indian and London markets.

The mode of preparing the ground for a vineyard is first to free it from all stumps and obstructions; and two ploughs and bullock teams are employed, one with four bullocks, and one eight. The team of four, attached to an ordinary plough, strikes out a furrow right and left, the same as the ordinary way of forming the crown of the land, driving the plough along the two first furrows again so as to break the ground to eight inches in depth, which is easily kept after once a start has been made. The second plough, worked by eight bullocks, is a skeleton plough, very strongly built, having no mould-board, is of extra depth from sole to beam, and has a strong double-winged share. This follows in the furrow of the first plough,

and stirs the soil to the total depth of eighteen inches, which is considered sufficient. This method enables the operator to trench-plough half an acre per day, taking into account the clearing of stone, and other delays, and when the trenching is completed, cross-harrowing with a heavy implement is done, and the surface brought down fine to prepare it for planting. Vineyards planted by farmers for their own use vary from five to twelve acres, which gives them sufficient of a wholesome beverage to last from year to year, and all proprietors of five acres of vines and over, are allowed, under liberal regulations, to distil the spirit from the lees or other refuse, and use it to fortify wines deficient in alcohol; but this applies more to the wines made in mountain districts, as the wines of the plains contain from twenty-five to thirty per cent. of natural spirit. Where wine-making is the object, vineyards vary from twenty to one hundred and fifty acres.

Planting.—The ground being ready, and the season arrived, such varieties are selected as the taste or experience of the owner dictates, and cuttings of well-ripened wood are selected, (always avoiding the latter growth), and as the ground has been worked to a depth of eighteen inches, the cutting should be twenty-one inches, being sunk to the bottom of the trenched land, and leaving two eyes above ground. The cutting is cut square off at the base of the lower eye, and as some varieties are prone to throw up suckers, it is dishudded between the lower and two top eyes.

The cuttings are let down to their places with a cross-handled iron bar, and the soil filled in tightly round the cutting in order that the rains may descend freely to the foot of the cutting and start it.

The number of plants per acre is regulated by the variety to be planted; it being necessary to keep strong and weak wooded varieties apart. Black Portugal, Frontignac, Shiroz, Mataro, Verdillho, Grenache, Madeira, White Muscat, and the Sherry grapes, are planted six feet apart each way; giving 1,225 plants to the acre. Stronger wooded varieties (table grapes) are planted eight feet apart each way, while Tokay, Carignan, Carbonel Savignon, and some Rhenish varieties, are planted four feet apart in the row, and six feet between the rows. The most successful modes of treatment for the plains is that of treating the vine as currant trees are in England. The plant rises on a stem not exceeding a foot in height, and is kept open in the centre, taking care to balance the plant in its external limbs, and in pruning the young wood is cut back to two eyes, carefully removing all decaying spurs, which convey rot to the heart of the plant and soon throw it out of health, and rag the fruit at crop time. The vines are not allowed to rise more than three feet, as succession wood is left, and the older limbs displaced. The plants are kept as symmetrical as possible, to ensure the cleaning of the land, and admit of perfect ventilation for maturing the crop. All ground wood is cut away, and the stem kept clear, as the shoots thrown off below fullbearing limbs rob the crop of its weight, and impoverish the fruit. For hill cultivation, the succession cutting is practised, i. e., wood of the last season's growth is laid in for bearing, and trained to the trellis, which is formed by posts being let in every thirty feet, and No. 4 wire passed through them, and tightly strained, never letting the bearing wood rise higher than thirty inches. The best young wood is laid in for the next season's crop, and all superfluous growth and laterals are displaced. It is customary to plant the vines running north and south, as the crop is best shaded from the meridian sun, and more equally ripened. The first method I have described has the advantage as to expense, as no staking or trellising is required, and is more easily worked.

The cost, per acre, of planting is, trenching, 30s. per acre; cuttings and planting do., including repairs of ploughs, harrows, etc., £3 10s.; total £5 per acre. It is very necessary to keep the ground free from weeds, as no vineyard is productive which is allowed to get foul.

In planting a vineyard, sloping and well-drained land should be selected, as grapes grown on swampy land are ill-flavoured, and subject to late frosts often destroying the crop. If the cuttings have been properly prepared and planted, very few failures take place, not more than ten per cent., and as the vine is very impatient of removal, it is better the cutting should be planted where it is to remain. The first season, cut the wood back to one eye, two eyes the second season, and so on till your plant has risen high enough for the stem, then let it have three limbs, forming as nearly as possible an equilateral triangle, from which the future head is formed. Be careful not to over-wood your plant, as you would only produce weak and barren growth. In the fifth year the vines should average eight pounds per plant; many varieties, such as Black Portugal and Greenache, give much more. The cost of ploughing, harrowing, pruning and cleaning cuttings, hoeing, through the season, is £3 per acre for a seven year old vineyard. I know of vineyards in South Australia, which, under good management, yield 300 gallons of wine per acre, which, at 2s. 6d. per gallon, give an income of £100 per acre, minus the ploughing, pruning, gathering, crushing and cellarage, for which together say £10 per acre, leaving £90 net. With more delicate varieties the produce per acre is not more than half; but the value of the wine is double, so the same result is arrived at.

Let not the Canadians be discouraged in vine culture, for I am sure, under careful treatment, good returns can be had. On a late visit to Niagara, I was pleased to see how luxuriant the wild vine grew close to the falls, and I gathered and ate some wild black grapes there which were far from being unpalatable. It occurred to me if a collection of cuttings from different varieties of the wild vine were made, which, by marking the plants now, could be easily done, (by noticing the difference in foliage), and properly cultivated, more useful varieties would be brought into bearing than by introducing foreign sorts, and I know raising the plants by cuttings, as I have described, will make bearing plants quite two years earlier than raising plants by separate eyes.

I trust that I have made myself sufficiently explicit to create an interest in vine culture in Ontario. I have only attempted to describe out-door treatment; but am fully conversant with that of the hothouse, and also of the manufacture and treatment of wines. Should any of your correspondents desire information in my power to impart, I shall with pleasure convey it; but would like to see some of the vineyards about Toronto.

EDWARD GILES.

23 Nassau St., Toronto.

On Grapes.

THE CHEAP CONSTRUCTION OF GLASS HOUSES.

Of course, it is well known to most of your readers that the varieties of grapes cultivated in the open air are those styled native grapes. These are principally crosses or hybrids between the wild grapes of America and the cultivated varieties of other countries, whilst those grown under glass are called foreign varieties. These latter require, in our short summer, the assistance of a glass protection, in order to equalize the heat of night and day, and to prolong the hot season by keeping out the late spring frosts, and those which ruthlessly destroy vegetation early in the autumn.

It is superfluous to state that it would not pay to grow in-door kinds if they were not vastly superior to those grown in the open air. The wholesale price of foreign grapes in Montreal is fifty cents per pound; the retail from one dollar twenty-five to seventy-cents—generally one dollar. The out-door kinds retail at from twelve and a half to thirty-seven and a half cents. I am told in Rochester they may be bought by the waggon load at five cents per pound in their season.

Glass houses are chiefly formed on two plans, either as a lean-to, with a south or southerly aspect, against some building already erected, or a double-pitched roof in an open space, or with the northern end attached to a house, fence, or other suitable place. The lean-to is certainly the most economical of glass; but in all the structures I have seen of this kind, the row of vines planted next the building to which the glass house is attached is of a very inferior growth to the one trained immediately along the glass. I would therefore most strongly

recommend parties about constructing, if they wish the greatest degree of excellence, to build on the double-pitched roof plan. A house sixteen feet long by ten feet wide may be built by sinking cedar posts five feet deep, so that there may be no danger of their being moved by frost, in two rows ten feet apart, eight feet apart in the rows. Up these nail down firmly, for plates, sixteen feet long scantling, three by four inches. The plates may be three or four inches above the surface of the soil. The rafters should be twelve and a half feet long, and placed four feet apart on the plate. It will be found a good plan, after putting up the first rafter, to nail the two first sashes lightly on before they are glazed, one on each side of the house. By this means the position of the second rafter will be obtained. The sash should come even with the centre of the second rafter. When you have this rafter in its place the lower end must be spiked down, and a strip temporarily nailed across the top, to keep that straight also. Sashes six feet by four can be procured at the mills here for one dollar each, and for the size of house mentioned sixteen will be required. These sashes must be five panes wide, of 8 by 10 glass. Besides these, there will be required a glass door for the south end, and two side sashes, and a three-cornered top sash. To glaze these it will take twenty-five pounds of putty and seven boxes of glass. This quantity, if not much broken, will leave half a box over for repairs. As the roof will be of a very steep pitch, it will be found best not to lap the glass in glazing, but to put it and to end in the sash, embedding the panes in soft putty. After they have been laid in the sash, which should have been previously primed with the best white lead and boiled oil, and a very little turpentine, they should be bradded in with two-eighth inch shoe-brads, to be obtained at the hardware store. The glazing can then be proceeded with. After it is finished, the glass should be shored up from the lower end, and a brad driven in to keep the glass from sliding down, and another coat of paint given over the wood and putty.

The rafters may be made by ripping down through the centre a twelve inch wide two inch thirteen feet plank, and as the sashes will be made of inch and three-quarter stuff, strips of that thickness, and two inches wide, must be nailed on the upper six feet of the rafters. The lower sash will be put on first, so as to project a little below the plate, and the upper sash should lap two inches over the lower sash. Care should be taken to have the foot of the rafter on a line with the outside of the plate. The rafters and plates should be planed smooth, and all knots covered with a composition called "knotting," to be obtained from the druggist, and then a good coat of white paint given before they are put in their places.

The bed for the vines should be principally made of sod off an old pasture, previously thrown into a heap. This may be turned over two or three times in the course of a month or two previous to its being put into the excavation made for it. A few barrels of ashes, ground bones, oyster-shells, and a load or two of well-rotted manure, may be advantageously added. The pit should be two and a half or three feet deep, and if the subsoil is at all inclined to be wet, the bottom should be concreted with mortar and gravel, or stone chips made by the cutters. These being for the most part flat, are easily worked in. A couple of feet of the floor should be plastered an inch deep, the stone then laid firmly on the mortar and smoothed over with another coat of plaster, and so on until the whole is completed. It is imperative that the concrete should have a slope of five or six inches in the sixteen feet to one corner, where a drain must be made to carry off the water. It is well to have three inches of loose stones, or a couple of rows of drain tiles, laid on the concreting, or a drain laid along the floor of loose bricks led out at the lower corner.

The wires for training the vines on should be put in vertically, fastened with small staples at the bottom, and run over a ridge-board at the top of the house, nailed under the rafters. These wires may again be stiffened in the centre by having a narrow piece of inch board, with saw cuts in it for the wires to pass through, nailed underneath the rafters six feet from the ground. After planting the vines it will be found of the greatest advantage if an inch of hen manure can be obtained to cover the surface of the vine bed; this will be washed into the light porous soil and have a most beneficial effect on the young vines. Down the centre of the house a foot-path should be laid of splints two inches wide and fourteen feet long, nailed at intervals of two feet across pieces of scantling two feet long, as it is of consequence that the soil should lie as light as possible in the border, and must on no occount be walked upon. At the same time, this kind of walk lets the light, air, and water through to the roots. Two of the top sashes, one at each side, should be made to slide down. Each of these sashes should have an iron bar attached firmly to itself, about one-third from the top end. This bar may be cut from an inch wide half-round bar, and holes should be drilled through it so as to allow of its being screwed to each bar of the sash with good stout screws. The centre of the bar should be rounded a little, as the cord used for holding the sash, when lowered, will be attached to it. The bar should not be so long as to touch the rafters, otherwise it will interfere with the sliding of the sash. The sashes being heavy, it is best to have on those which slide four small iron rollers, to be obtained at the hardware store, let into the sash eight inches from each corner. These will run on the rafter, and assist materially, in raising and lowering them, to regulate the temperature of the house. A rope is tied to the iron bar, and run through a screw pulley attached to the top of the house, and from thence brought down and attached to a cleet nailed to a rafter. This rope can then be shortened or lengthened as required. The rope being firmly attached, the sash is let down from the outside, being kept in its place when pushed up by a piece of wood two feet long, made to work on a screw driven through its lower end, and attached to the frame of the next sash to the one the sliding sash comes down over.

A vinery of this description, having an area of 12 by 32 feet of glass, can be built, by the party doing most of the work himself, for $63. A neighbour of mine constructed one with the aid of an architect, and letting out the work by tender, the area of which is very little greater, and the work on it simpler, it being a lean-to roof. It cost him two hundred and twenty-five dollars, and is not yet painted!

Mine can be extended from year to year at any time, which is another great advantage I possess. I give below my figures:—

For concreting two loads of stone, 25c. per load	$0 50
Three bushels of lime, 25c	75
Man for mixing mortar and concreting	1 50
Man and horse half a day, hauling sods	1 00
Two loads of manure, 25c	50
Sixteen sashes, $1	16 00
Glass door and three end sashes	6 00
Seven boxes glass, $2 12½	14 87
Knotting, 15c. Hinges, 10c	25
Eight small rollers for sash	25
Lock, 65c. Sash cord, 25c	90
Two screw pulleys	16
Two iron sash bars, 25c	50
Scantling and boards	5 00
Seven pounds galvanized wire, 10c	70
Man to glaze sashes	6 00
Sprigs for glazing	17
Nine vines, 50c	4 50
75 pounds of putty, 4c	3 00
	$62 55

P. E. B.

Ottawa, Sept. 7th, 1870.

Profit of Grape Culture.

Mr. C. L. Hoag, of Lockport, N. Y., has been engaged in the cultivation of the grape vine for many years. He is well known to the writer, not only as a very successful cultivator, but as a gentleman of careful observation, whose statements are not made without ample foundation, and who would most scrupulously avoid everything that could possibly mislead.

At a meeting of the Western New York Horticultural Society, Mr. Hoag, speaking on the subject of crops and sales of grapes, made some statements which were most bewilderingly reported—a very common occurrence. To correct the impression these errors of the reporters might occasion, Mr. Hoag writes to the *Rural New Yorker* a very interesting letter, from which we give our readers some of the items.

He states that, after twenty years' experience, he has found the grape more profitable than any other fruit grown in that section, but does not advise cultivators to attempt the grape except in localities where the grape succeeds, and on land well adapted to the grape, and that requires no underdraining. His Iona vines, planted ten feet by six, 726 vines to the acre, produced the fourth year, 1868, from ten to fourteen pounds per vine, the fruit having been

weighed when gathered. This crop was sold for thirty cents per pound, the offer made by the Hammondsport Wine Company of twenty cents per pound having been declined. But, taking the crop at ten pounds to the vine, and the price at twenty cents per pound, the result would be $1,450 per acre.

Mr. L. H. Babcock, President of the Niagara County (N.Y.) Agricultural Society, has a vineyard of Delaware vines which produced five tons per acre.

Mr. J. Craine, of Lockport, stated that his vineyard of the Wilder Grape (Rogers' No. 4) produced 9,000 pounds per acre, and the fruit was sold for twenty-five cents per pound in New York City.

Mr. N. Ringueberg, also of Lockport, stated to Mr. Hoag that his Delaware vineyard of two acres, planted two years, produced last year 1,500 pounds of well-ripened fruit per acre.

But none of these gentlemen approve of heavy cropping of vines, either young or old. Three tons per acre, as an average each year, is considered quite enough for well established vineyards. All of the vineyards above referred to are growing in open fields, fully exposed, not in gardens with the usual surroundings.

He does not expect as high prices for grapes in the future, but does not expect to sell good, well ripened, selected grapes for less than ten cents per pound during the next ten years, and believes that where grapes succeed they can be grown at three cents per pound with as much profit as wheat at two dollars per bushel.

Mr. De Long, of California, tells Mr. Hoag that grapes can be grown there at a cent and a half per pound with as much profit as wheat at $2 per bushel.

Strawberry Growing for Profit.

The *Horticulturist* for August expresses the opinion that the profits of strawberry culture have been greatly exaggerated, and estimates the average cost of growing, picking, and marketing strawberries at seven cents per quart, so that all the producer gets is what he may be able to realize over that sum. This estimate may be a little more than the cost to the Canadian grower, but we have become convinced from actual experience that the grower is reaping but a very small return for his risk and labour when he gets less than ten cents per quart.

It is a very easy matter to have the small fruit business overdone, as the history of that business for the last two years amply demonstrates. Before long we shall find it settling down in the hands of men of experience and skill. Men without these qualifications have rushed into the business, and have found that there were difficulties they did not anticipate—that the golden harvest did not fall into their lap. But some things have been learned by the failure of the ignorant and over-sanguine, and wise men will profit by them. Among other things, it has been ascertained that the largest crops are grown on clay soil, well drained and well manured, and that light soil cannot compete with it. It has also been ascertained that much depends upon the condition in which fruit comes to market, and that it pays in the long run to send only choice fruit in neat packages. And last, but by no means least, that it is of the utmost importance to cultivate only so much as can be cultivated, gathered and marketed in the best style.

What is a Flower?

Flowers are merely leaves, so arranged as to protect the vital organs within them, and coloured so as to attract insects to scatter the fertilizing pollen, and to reflect and absorb the light and heat of the sun for ripening the seed.

We see the whole gradual process of the change of the common leaf in all the parts of a flower, most beautifully displayed in the flower of the common white pond lily. The outermost circle of petals is greenish, approaching the herbaceous texture and colour of the calyx; the next circles are purer and more succulent, and the innermost ones are snowy white, entirely cellular, and begin to show rudiments of an anther at their points. Gradually the petals become smaller and narrower, while the anthers on their summits become more distinct, until at length the usual thread-like filaments, and golden dusty anthers of perfect stamens appear in the heart of the flower.—*The Gardener.*

Setting out Orchards in Autumn.

Notwithstanding all that has been said against the practice of planting apple trees in the fall, and the many statements given of failures of such trees to grow, I am still inclined to think the practice a good one, and certain to succeed in all cases where the soil is in a favourable condition, the trees healthy and vigorous, and the work of planting thoroughly well done. As is generally the case, those who fail through any cause (and in nine cases out of ten the cause is their own carelessness) are sure to cry out and condemn the practice, while those who are careful and succeed make no noise about the matter.

Three requisites are necessary to ensure success in the work of planting out orchards in the fall of the year:—

1st. The trees to be planted out should not be removed from where they grow in the nursery rows until their present season's growth of wood has become ripened and firm. Many agents are in such a hurry to begin their deliveries of trees that they persuade the nurseryman to take them up in the fall at an earlier date than he could conscientiously recommend. Such trees, full of sap arrested in its course by untimely removal, are very apt to get badly frozen during the winter, in patches all over the tree, from the roots to the top.

2nd. The ground to be planted as an orchard must be thoroughly well prepared, and if not already underdrained, must be ridged and furrowed in such a way as to ensure that no water shall remain on the surface anywhere near the trees, to be frozen if a sudden cold snap should come later in the fall.
